## Contents

CONTENTS ..... 2
1 EXECUTIVE SUMMARY. ..... 13
2 INTRODUCTION ..... 22
3 METHODS ..... 24
3.1 Data Collection ..... 24
3.2 Data transfer and linking to hospitalisation records ..... 26
3.3 Data analysis ..... 27
3.3.1 Construction of applicant and tenant cross-section ..... 27
3.3.2 Key variables ..... 27
3.3.3 Crowding Measures ..... 28
3.3.4 Analysis of hospitalisation data ..... 30
4 QUALITY AND COMPLETENESS OF DATA ..... 39
4.1 Needs assessment interviews ..... 39
4.1.1 Interviews by month ..... 39
4.1.2 Response to the ethnicity question in the NA interview ..... 42
4.2 IRR assessment ..... 42
4.2.1 Interviews by month ..... 43
4.2.2 Completeness of the data ..... 44
4.2.3 Voluntary response to the smoking question ..... 44
4.2.4 Response to the ethnicity question ..... 46
4.3 Quality of data matching ..... 46
4.3.1 Completeness of data matching ..... 47
4.3.2 Potential errors with data matching and the NHI ..... 48
4.3.3 Characteristics of matched and un-matched participants ..... 49
4.4 Other data issues ..... 49
4.4.1 Data entry errors ..... 49
4.4.2 Comparison of ethnicity data from multiple sources ..... 50
5 CHARACTERISTICS OF THE APPLICANTS ..... 52
5.1 Household Demographics ..... 52
5.1.1 Age Distribution of the housing applicants ..... 52
5.1.2 Sex distribution of the housing applicants ..... 53
5.1.3 Ethnic Characteristics of the housing applicants. ..... 53
5.2 Household Structure and income ..... 54
5.2.1 Structure of the applicant households ..... 54
5.2.2 Income of the applicant households ..... 55
5.3 Crowding Level ..... 56
5.3.1 Household Size ..... 56
5.3.2 Number of bedrooms in the applicant house ..... 59
5.3.3 Crowding levels of the applicant dwelling ..... 60
5.3.4 Self reported duration in current situation ..... 63
5.3.5 Duration as housing applicant ..... 65
5.4 Characteristics of high and moderate priority applicants ..... 66
6 CHARACTERISTICS OF THE TENANTS ..... 69
6.1 Household demographics ..... 69
6.1.1 Age distribution of the tenants ..... 69
6.1.2 Sex distribution of the tenants ..... 70
6.1.3 Ethnic characteristics of the tenants ..... 70
6.2 Household structure and income. ..... 71
6.2.1 Structure of the tenant households ..... 71
6.2.2 Income of the tenant households ..... 72
6.3 Tobacco smoking ..... 73
6.3.1 Active smoking ..... 73
6.3.2 Smoking households ..... 74
6.4 Crowding level ..... 76
6.4.1 Household size ..... 76
6.4.2 Number of bedrooms in the tenant property ..... 77
6.4.3 Crowding levels of the tenant households ..... 79
6.4.4 Duration in current accommodation ..... 81
7 COMPARISON OF THE HOUSING APPLICANTS AND TENANTS ..... 83
7.1 Household demographics, structure and income ..... 83
7.2 Household size and crowding levels ..... 83
8 LONGITUDINAL ANALYSIS OF APPLICANT AND TENANT POPULATIONS 88
8.1 Flows of households through HNZC processes ..... 88
8.2 Repeated measurements of households ..... 88
8.3 Characteristics of high and moderate priority applicants ..... 91
8.4 Reasons for applicants exiting the waiting list ..... 93
9 HOSPITALISATIONS IN HOUSING APPLICANTS AND TENANTS ..... 94
9.1 Analytical steps in interpreting hospitalisation data ..... 94
9.1.1 Removing non-hospitalisations and overseas visitors ..... 94
9.1.2 Selecting admission types ..... 94
9.1.3 Select whether to include principal and additional diagnosis ..... 98
9.1.4 Selecting and removing irrelevant hospitalisations ..... 98
9.1.5 Select whether to include repeat admissions ..... 99
9.1.6 Select conditions of interest ..... 101
9.1.7 Calculate disease rates - Duration of time in cohort ..... 101
9.2 Characteristics of hospitalisations ..... 103
9.2.1 Hospitalisation rates in housing applicants, tenants and other NZ population ..... 103
9.2.2 Characteristics of those hospitalised ..... 105
9.2.3 Comparison of hospitalisation rates by major disease categories. ..... 110
9.2.4 Comparison of hospitalisation rates by selected diseases ..... 112
9.2.5 Age-ethnicity standardised causes of admissions ..... 130
9.2.6 Comparison of applicants with recent tenants ..... 134
9.2.7 Comparison of hospitalisation rates by duration of tenancy ..... 136
9.2.8 Comparison of hospitalisation rates by prioritisation ..... 140
9.2.9 Sensitivity analysis based on restricting to overnight admissions ..... 141
9.2.10 Potentially avoidable hospitalisations ..... 142
9.2.11 Hospitalisation rates by crowding level ..... 143
9.2.12 Hospitalisation rates for active smoking adults ..... 145
9.2.13 Hospitalisation rates for passive smoking children ..... 148
10 DISCUSSION ..... 151
10.1.1 Main findings ..... 151
10.1.2 Implications ..... 155
10.1.3 Limitations ..... 156
10.1.4 Further work ..... 156
11 REFERENCES ..... 157
12 APPENDICES ..... 158

## List of Tables

Table 1.1: Summary of characteristics of housing applicant and tenant households at 30th June 2005, compared with New
Zealand population (2001 census)
Table 2.1: Classification of factors affecting the health of HNZC applicants and tenants and their measurement as part of the Housing, Crowding and Health Study ..... 23
Table 3.1: HNZC regional office structure, 2005 ..... 24
Table 3.2: The revised Jensen Index ..... 28
Table 4.1: Number of needs assessment interviews by month, February 2003 to June 2005 ..... 40
Table 4.2: Completeness of key crowding variables from the needs assessment interview, February 2003 to June 2005 ..... 41
Table 4.3: Number of IRR forms completed by month, February 2003 to June 2005 ..... 43
Table 4.4: Completeness of key variables from the IRR form, February 2003 to June 2005 ..... 44
Table 4.5: Characteristics of people completing the smoking questions on the IRR form, April 2003 to June 2005 ..... 45
Table 4.6: Comparison of cohort members based on their NHI to see how many have multiple housing reference (ID2) numbers, (May 2003 to June 2005) ..... 48
Table 4.7: Comparison of cohort members based on their housing reference (ID2) number to see how many have multiple NHI numbers, (May 2003 to June 2005) ..... 48
Table 4.8: Comparison of ethnicity recording characteristics across different data sources (HNZC, NZHIS, Census) ..... 50
Table 4.9: Characteristics of cohort participants who were matched with NHI numbers and those who were un-matched, May 2003 to June 2005 ..... 51
Table 5.1: Summary statistics for the age distribution of people in applicant households at June 2005 ..... 53
Table 5.2: Sex distribution of people in housing applicant households at June 2005 ..... 53
Table 5.3: Ethnicity of people in housing applicant households at June 2005, based on exclusive and inclusive coding ..... 53
Table 5.4: Applicant household structure ..... 54
Table 5.5: Applicant household numbers at June 2005 ..... 54
Table 5.6: Summary statistics of the total weekly applicant household income ..... 55
Table 5.7: Number of households with members receiving a Government benefit ..... 56
Table 5.8: Summary statistics for the applicant household size ..... 57
Table 5.9: Applicant household size, including contribution from non-applicants living in the same house at June 2005 ..... 57
Table 5.10: Applicant household size comparing applicants who share with non-applicants to those who do not share at June 2005 ..... 58
Table 5.11: Number of bedrooms in house used by housing applicants at June 2005 ..... 59
Table 5.12: Summary statistics for the number of bedrooms in the applicant house ..... 59
Table 5.13: Summary statistics for the number of people per bedroom in the applicant house ..... 61
Table 5.14: Crowding levels calculated using the people per bedroom formula ..... 61
Table 5.15: Summary statistics for the number of people per bedroom (Method 1) comparing applicants who share with other people to those who do not at June 2005 ..... 62
Table 5.16: Mean room deficit for housing applicants, based on CNOS, summary statistics at June 2005 ..... 63
Table 5.17: Housing applicant bedroom deficit measured against CNOS at June 2005 ..... 63
Table 5.18: Length of time applicants have been living in current situation i.e. with this number of people and in current house at the time of the NA interview ..... 64
Table 5.19: Summary statistics for the duration in accommodation ..... 64
Table 5.20: Summary statistics for the length of time the current applicants have been on the waiting list ..... 65
Table 5.21: Prioritisation for HNZC housing ..... 66
Table 5.22: Characteristics of high and moderate priority applicants at June 2005 ..... 68
Table 6.1: Summary statistics for the age distribution of tenants ..... 70
Table 6.2: Sex distribution of people in tenant households at June 2005 ..... 70
Table 6.3: Ethnicity of people in tenant households, based on exclusive and inclusive coding at June 2005 ..... 71
Table 6.4: Tenant household structure ..... 71
Table 6.5: Tenant household numbers at June 2005 ..... 72
Table 6.6: Summary statistics of the total weekly tenant household income ..... 72
Table 6.7: Number of household members receiving a benefit ..... 73
Table 6.8: Prevalence of reported smoking in adult tenants at June 2005 ..... 74
Table 6.9: Prevalence of reported household smoking status of tenants at June 2005 ..... 75
Table 6.10: Prevalence of reported household smoking status of tenants, by household characteristics at June 2005 ..... 75
Table 6.11: Tenant household size at June 2005 ..... 76
Table 6.12: Summary statistics for household size ..... 77
Table 6.13: Number of bedrooms in tenant houses at June 2005 ..... 78
Table 6.14: Summary statistics for the number of bedrooms ..... 78
Table 6.15: Tenant household summary statistics for the people per bedroom ..... 79
Table 6.16: Tenant household crowding level, as measured by number of people per bedroom at June 2005 ..... 79
Table 6.17: Tenant household summary statistics for the CNOS ..... 80
Table 6.18: Tenant household crowding level, as measured by the CNOS bedroom deficit at June 2005 ..... 80
Table 6.19: Summary statistics for the duration in accommodation ..... 81
Table 6.20: Length of time the tenants have been living in their current accommodation, at June 2005 ..... 81

Table 7.1: Characteristics of housing applicants and housing tenants at June 2005, compared with total NZ population (2001 census)
Table 7.2: Household size and crowding characteristics of housing applicant and tenant households June 2005, compared with New Zealand population (2001 census)
Table 8.1: Summary of applicant and tenant movement at June 2005 ...................................................................................... 89
Table 8.2: Changes for households with more than one observation at June 2005..................................................................... 90
Table 8.3: Movement of the applicants through the various states at June 2005.......................................................................... 92
Table 8.4: Priority status of the applicants for the three simplest flows ${ }^{1}$ at June 2005 .................................................................. 92
Table 8.5: Reasons for exiting for all applicant exit records ${ }^{1}$...................................................................................................... 93
Table 9.1: ‘Non-hospitalisation' events filtered out of hospitalisation data, May 2003 to June 2005 ......................................... 94
Table 9.2: Hospitalisations classified according to admission types, May 2003 to June 2005 (Filtered to exclude non
hospitalisations and overseas cases) .............................................................................................................................. 95
Table 9.3: Number of diagnostic codes recorded for hospitalised cases, May 2003 to June 2005 (Filtered to exclude non hospitalisations, overseas visitors and waiting list admissions).98

Table 9.4: Selected irrelevant conditions, May 2003 to June 2005 (filtered to exclude non hospitalisations, overseas visitors and waiting list admissions)
.99
Table 9.5: Frequency of admissions, June 2003 to May 2005 (filtered to exclude non hospitalisations, overseas visitors and waiting list admissions and irrelevant conditions)

100
Table 9.6: Proportion of hospitalisations excluded by different readmission filters, May 2003 to June 2005 (filtered to exclude non hospitalisations, overseas visitors and waiting list admissions and irrelevant conditions)........................................ 100
Table 9.7: Number of individuals in cohort with overlapping time spent as housing applicants and tenants, May 2003 to June 2005 (based on total HNZC data)
Table 9.8: Summary statistics for duration of time in cohort, May 2003 to June 2005 (with adjustment for applicants and tenants with overlapping periods)103

Table 12.1: Population used for age-ethnicity standardisation, based on age-ethnicity structure of HNZC population at June 2005, compared with NZ Census population 2001
Table 12.2: Distribution of admission types within DHBs for cohort study population (applicants and tenants), May 2003 to June 2005.
Table 12.3: Distribution of admission types within DHBs for other $N Z$ population, May 2003 to June 2005 ......................................................................................................................................................
Table 12.4: Hospitalisation numbers and age-standardised rates in cohort population (applicants and tenants) compared with other NZ population, according to successive levels of filtering and major admission categories, May 2003 to June 2005

Table 12.5: Hospitalisation numbers and age-standardised rates in housing applicants compared with housing tenants, according to successive levels of filtering and major admission categories, May 2003 to June 2005 Table 12.6: Total hospitalisation numbers and crude rates in housing applicants, housing tenants and other NZ population, according to key demographic characteristic, May 2003 to June 2005

162 12.7: Hospitalisation numbers and crude rates in housing applicants, housing tenants and other NZ population, using standard filter (excludes overseas visitors, non-hospitalisations, waiting list admissions, irrelevant conditions and onemonth readmissions), according to key demographic characteristic, May 2003 to June 2005.
Table 12.8: Hospitalisation numbers and age-specific or age-standardised rates in cohort population (applicants and tenants) compared with the other $N Z$ population, based on principal diagnosis and standard filter ${ }^{1}$, according to key demographic characteristic May 2003 to June 2005.

165
Table 12.9: Hospitalisation numbers and age-standardised rates in housing applicants compared with housing tenants, based on principal diagnosis and standard filter ${ }^{1}$, according to key demographic characteristic May 2003 to June 2005........ 166
Table 12.10: Hospitalisation numbers and age-standardised rates in applicants compared with tenants, based on principal diagnosis and standard filter ${ }^{1}$, according to Equivalised Income, May 2003 to May 2005
Table 12.11: Hospitalisation numbers and age-standardised rates in tenants, based on principal diagnosis and standard filter ${ }^{1}$, according to SAU average NZDep2001, May 2003 to May 2005.

167
Table 12.12: Hospitalisation numbers and age-standardised rates in applicants compared with tenants, based on principal diagnosis and standard filter ${ }^{1}$, according to HNZC region, May 2003 to June 2005
Table 12.13: Distribution in housing tenants, compared with Total New Zealand residents ${ }^{1}$, according to Urban and Rural 168
Table 12.14: Hospitalisation numbers and age-standardised rates in applicants, compared with the tenants, based on principal diagnosis and standard filter ${ }^{1}$, according to Seasons, May 2003 to May 2005
Table 12.15: Hospitalisation numbers and age-standardised rates in cohort population (applicants and tenants) compared with the other $N Z$ population, according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005.
Table 12.16: Hospitalisation numbers and age-standardised rates in housing applicants compared with housing tenants, according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005
Table 12.17: Hospitalisation numbers and age-standardised rates ${ }^{1}$ in cohort population (applicants and tenants) compared with the other $N Z$ population, according to selected diseases of interest, based on principal diagnosis and standard filter ${ }^{2}$, May 2003 to June 2005.
Table 12.18: Hospitalisation numbers and age-standardised rates ${ }^{1}$ in housing applicants compared with housing tenants, according to selected diseases of interest, based on principal diagnosis and standard filter ${ }^{2}$, May 2003 to June 2005... 176
Table 12.19: Comparison of rates and rate ratios for housing applicants and housing tenants with the other NZ population, using different measures of rate, based on principal diagnosis and standard filter, ${ }^{1}$ May 2003 to June 2005

Table 12.20: Hospitalisation numbers and age-ethnicity-standardised rates in cohort population (applicants \& tenants) compared with Other New Zealand population, according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$, May 2003 to June 2005
Table 12.21: Hospitalisation numbers and age-ethnicity-standardised rates in housing applicants compared with housing tenants, according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$, May 2003 to June 2005
$\qquad$

Table 12.22: Hospitalisation numbers and age-ethnicity-standardised rates ${ }^{1}$ in cohort population (applicants and tenants)
compared with the other $N Z$ population, according to selected diseases of interest, based on principal diagnosis and
standard filter ${ }^{2}$, May 2003 to June 2005

Table 12.23: Hospitalisation numbers and age-ethnicity-standardised rates ${ }^{1}$ in housing applicants compared with housing tenants, according to selected diseases of interest, based on principal diagnosis and standard filter ${ }^{2}$, May 2003 to June 2005
Table 12.24: Hospitalisation numbers and age-standardised rates in housing applicants (who subsequently became tenants) compared with housing tenants (during their first 12 months of tenancy time), according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$, May 2003 to June 2005.
Table 12.25: Hospitalisation numbers and age-standardised rates in housing applicants (who subsequently became tenants) compared with housing tenants (during their first 12 months of tenancy time), according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$, May 2003 to June 2005.
Table 12.26: Hospitalisation numbers and age-standardised rates in housing tenants according to duration as tenants, for major disease categories, based on principal diagnosis and standard filter ${ }^{1}$, May 2003 to June 2005196

Table 12.27: Hospitalisation numbers and age-standardised rates in housing tenants according to duration as tenants, for selected diseases, based on principal diagnosis and standard filter ${ }^{1}$, May 2003 to June 2005197

Table 12.28: Age-standardised hospitalisation rates in Sub-groups of housing applicants ( $\mathrm{A}+\mathrm{B}, \mathrm{C}+\mathrm{D}$ ) compared with Tenants and other NZ population, May 2003 to June 2005

203
Table 12.29: Sensitivity analysis: Hospitalisation numbers and age-standardised rates in cohort population (applicants \&
tenants) compared with Other New Zealand population, according to major disease categories, based on principal
diagnosis and standard filter ${ }^{1}$ and excluding all day cases, May 2003 to June $2005 \ldots . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~$ 204
Table 12.30: Sensitivity analysis, Hospitalisation numbers and age-standardised rates in housing applicants compared with housing tenants, according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$ and excluding all day cases, May 2003 to June 2005
Table 12.31: Sensitivity analysis: Hospitalisation numbers and age-standardised rates in cohort population (applicants \& tenants) compared with Other New Zealand population, a according to selected diseases of interest, based on principal diagnosis and standard filter ${ }^{1}$ and excluding all day cases, May 2003 to June 2005.

206
Table 12.32: Sensitivity analysis: Hospitalisation numbers and age-standardised rates in housing applicants compared with housing tenants, according to selected diseases of interest, based on principal diagnosis and standard filter ${ }^{1}$ and excluding all day cases, May 2003 to June 2005
Table 12.33: Potentially avoidable hospitalisations (PAH), age-standardised rates in housing applicants compared with housing tenants and the other NZ population, based on principal diagnosis and minimal filtering ${ }^{1}$, May 2003 to June 2005 ..... 214
Table 12.34: Hospitalisation numbers, standardised rates and rate ratios in crowded compared with uncrowded households, based on principal diagnosis and standard filter, ${ }^{1}$ May 2003 to June 2005.
Table 12.35: Hospitalisation numbers, standardised rates and rate ratios according to crowding level, based on principal diagnosis and standard filter, ${ }^{1}$ May 2003 to June 2005.

216
Table 12.36: Hospitalisation numbers, age-ethnicity-standardised rates and rate ratios in crowded compared with uncrowded housing applicant households, according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005.
Table 12.37: Hospitalisation numbers, age-ethnicity-standardised rates and rate ratios in crowded compared with uncrowded housing tenant households, according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005.
Table 12.38: Hospitalisation numbers, age-ethnicity-standardised rates and rate ratios in crowded compared with uncrowded cohort (applicant and tenant) households, according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005. 219
Table 12.39: Hospitalisation numbers, age-ethnicity-standardised rates and rate ratios in crowded compared with uncrowded cohort (applicant and tenant) households, according to specific diseases, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005220

Table 12.40: Hospitalisation numbers, standardised rates and rate ratios according to active smoking tenants (over 19 years), based on principal diagnosis and standard filter, ${ }^{1}$ May 2003 to June 2005
224

Table 12.41: Hospitalisation numbers, standardised rates and rate ratios according to passive smoking (under 15 years), based on principal diagnosis and standard filter, ${ }^{1}$ May 2003 to June 2005.
Table 12.42: Hospitalisation numbers, age-standardised rates and rate ratios in active smoking tenants compared with non smoking tenants, according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005.

225
Table 12.43: Hospitalisation numbers, age-ethnicity-standardised rates and rate ratios in active smoking tenants compared with nosmoking tenants, according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005

226
Table 12.44: Hospitalisation numbers, age-standardised rates and rate ratios in active smoking tenants compared with nosmoking tenants, according to specific diseases, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005

Table 12.45: Hospitalisation numbers, age-ethnicity-standardised rates and rate ratios in active smoking tenants compared with nosmoking tenants, according to specific diseases, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005
 nosmoking tenants, according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005235

Table 12.47: Hospitalisation numbers, age-ethnicity-standardised rates and rate ratios in passive smoking tenants compared with nosmoking tenants, according to major disease categories, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005.
Table 12.48: Hospitalisation numbers, age-standardised rates and rate ratios in passive smoking tenants compared with nosmoking tenants, according to specific diseases, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005
Table 12.49: Hospitalisation numbers, age-ethnicity-standardised rates and rate ratios in passive smoking tenants compared with nosmoking tenants, according to specific diseases, based on principal diagnosis and standard filter ${ }^{1}$ May 2003 to June 2005

## List of Figures

Figure 3.1: Flow of people between the other $N Z$ population and housing applicant and housing tenant populations ..... 25
Figure 3.2 Steps involved in the transfer of housing tenant and applicant data from HNZC to WSM, including its linking to hospitalisation data by NZHIS ..... 26
Figure 3.3 Steps involved in analysis of hospital discharge data. ..... 31
Figure 4.1: Response rates for the key crowding variables across time ..... 41
Figure 4.2: Response to ethnicity question on NA interview by month, February 2003 to June 2005 ..... 42
Figure 4.3: Response to smoking question on IRR form by month, February 2003 to June 2005 ..... 44
Figure 4.4: Response to ethnicity question on IRR form by month, February 2003 to June 2005 ..... 46
Figure 4.5: Match rate by month, May 2003 to June 2005 ..... 47
Figure 5.1: Age distribution of the applicant household members at June 2005 ..... 52
Figure 5.2: Income of the applicant households, based on total household income per week at June 2005 ..... 55
Figure 5.3: Number of people in the applicant households at June 2005 ..... 58
Figure 5.4: Number of bedrooms in the applicant house (excluding four values $>10$ ) at June 2005 .....  60
Figure 5.5: Crowding levels in the applicant households measured using people per bedroom at June 2005 ..... 62
Figure 5.6: Applicants duration in their current accommodation at the time of the NA interview at June 2005 ..... 64
Figure 5.7: Duration the cross section of applicants have been on the waiting list at June 2005 ..... 66
Figure 6.1: Age distribution of tenant household members at June 2005 ..... 69
Figure 6.2: Income of the tenant households per week (excluding 6 values greater than $\$ 1500$ ) at June 2005. ..... 73
Figure 6.3: Number of people in the tenant household at June 2005 ..... 77
Figure 6.4: Number of bedrooms in the tenant households at June 2005 ..... 78
Figure 6.5: Tenant crowding measured using people per bedroom at June 2005 ..... 80
Figure 6.6: Duration of stay in current accommodation for the tenants at June 2005 ..... 82
Figure 7.1: Comparison of the average people per household at June 2005 ..... 86
Figure 7.2: Comparison of the average number of bedrooms at June 2005 ..... 86
Figure 7.3: Comparison of the average people per bedroom at June 2005 ..... 87
Figure 7.4: Comparison of the percentage of households with bedrooms deficit of one or more at June 2005. ..... 87

## Acknowledgements

He Kainga Oranga, Housing and Health Research Programme would like to acknowledge support from Housing New Zealand Corporation (HNZC), the New Zealand Health Information Service (NZHIS) and the Health Research Council, which has enabled the establishment and operation of this study.

We wish to particularly acknowledge the following current and former staff at HNZC: Michael Lennon, Helen Fulcher, Blair Badcock, Keith Johnson, Louise Hoather, Brian Reeve, Garry Williams, Linda Watkins, Selina Gentry, Virginia Keast, Ian Bourke, Tom Bridgman, and Bernadette Doolan. Staff at NZHIS who have assisted the study include Chris Lewis and Jim Fraser.

We also wish to thank colleagues who have contributed to establishment of this study while working with us at He Kainga Oranga: Jasminka Milosevic, Robin Turner, and Charlotte Kieft.

## 1 Executive Summary

## Introduction

The Housing, Crowding and Health Study aims to investigate the relationship between household crowding levels and hospitalisation rates in a large cohort of Housing New Zealand Corporation (HNZC) applicant and tenant households. This report presents study findings based on analysis of applicant and tenant data obtained over the 29 -month period from February 2003 to June 2005. It also contains an analysis of linked hospitalisation data covering a 26-month period (May 2003 to June 2005).

## Methods

This study is based on data collected by HNZC as part of its routine business operations. Information on housing applicants is recorded on a Needs Assessment (NA) record form. Most housing tenants complete an annual Income Related Rent (IRR) application form. These processes allow collection of information on exposure to housing conditions in a large cohort of households. They also allow for collection of information on important confounding factors, notably age, ethnicity, household income, and tobacco smoke exposure. Household crowding is measured using occupancy (number of people per household), density (people per bedroom) and according to the Canadian National Occupancy Standard (CNOS).

This research uses, as the measure of health outcomes, hospitalisations for infectious diseases and other conditions. The HNZC data are forwarded to the New Zealand Health Information Service (NZHIS) for linking to their national health index number (NHI). The data are then anonymised (including encrypting the NHI) and passed to the researchers for analysis. During establishment of the study a number of changes were made to HNZC data collection processes. These changes included:

- Expanded ethnicity recording fields, consistent with those used by Statistics New Zealand, on both the NA and IRR forms.
- Additional crowding questions on NA form (numbers of other non-applicant people living in the house, total number of bedrooms, number of other rooms being used as bedrooms, and duration of time living in this situation in this house).
- Addition of a voluntary smoking question for adults, on the IRR form.

The study commenced operation in February 2003. Currently the investigators have data on applicants and tenants from February 2003 through to June 2005 and matched hospitalisation data for May 2003 to June 2005. This report presents an analysis of both these sets of data.

Analysis of hospitalisation data requires several additional steps: filtering out nonhospitalisations and irrelevant conditions; specifying the range of conditions of interest; deciding whether to include just principal (first listed) or additional diagnoses; filtering repeat admissions; identifying events and person days that occurred during the time the person was in the cohort; and calculating disease rates. The standard filter removed 'non-hospitalisations' and overseas visitors, waiting-list admissions, and 'irrelevant conditions' (day-case diagnostic procedures, day case treatment of chronic conditions such as renal dialysis, maternity, perinatal, and disability support service (DSS) admissions). The analysis was based on
principal diagnosis with a one-month readmission exclusion (filtering out of hospitalisations occurring within one month of the original admission and having the same 3-digit ICD. 10 clinical code recorded as the principle diagnosis). Age-standardised rates were calculated to take account of the different age structures of housing applicant and housing tenant populations compared with the New Zealand population not in this cohort (other NZ). Analyses were repeated using age-ethnicity standardised rates to further adjust for the relatively high proportion of Maori and Pacific People in the cohort population. Rate ratios (RR) and 95\% confidence intervals ( $95 \% \mathrm{CI}$ ) were calculated using standard method for age-standardised and age-ethnicity standardised data.

## Results

Response rates: By June 2005 the new ethnicity field on the IRR form was being completed by $95 \%$ of tenants (an increase from $90 \%$ in July 2004). The voluntary smoking question on the IRR was filled in for $63 \%$ of adults (an increase from $57 \%$ in July 2004). Both response rates appear to be levelling off at around these levels. The additional key crowding variables added to the NA interview had response rates of $100 \%$ following a modification to the Rentel database (released on 22 August 2004).

Characteristics of housing applicants and housing tenants: Cross sectional comparisons were made between housing applicants, housing tenants and the total New Zealand population (see summary table 1.1). There are differences in demographics, income and crowding levels between these three groups:

- Half of the people living in applicant and tenant households are less than 20 years of age.
- Maori and Pacific people make up $60.2 \%$ of applicant and $70.4 \%$ of tenant households.
- One adult with children households make up $42.7 \%$ of the applicant households, compared with $35.5 \%$ of the tenant households.
- Seventy-five percent of the applicants have an equivalised household income less than or equal to $\$ 315$ per week. Seventy-five percent of the tenants have an income of $\$ 353$ or less per week.
- In $78.7 \%$ of applicant households, at least one household member is receiving a benefit, compared with $91.1 \%$ of tenants.
- About a third of tenants (31.7\%) and a half of NZ Maori tenants (49.7\%) smoke, compared with a quarter of the NZ population. About $44.5 \%$ of households include one or more smokers, based on those that provided such information.
- Housing applicants had larger households and higher levels of crowding (46.1\% one or more bedrooms short) than housing tenants ( $23.6 \%$ ), and both groups had higher crowding levels than the total New Zealand population (5.1\%).
- About $37.9 \%$ of housing applicants were living with other families ('double-ups') and they reported particularly high levels of household crowding ( $79.8 \%$ of these 'double-up', households were classified as crowded using the CNOS, compared with $26.1 \%$ of applicant households who were not sharing).
- The average length of time living in this situation (i.e. in this house with this number of people) for applicants on the waiting list was 73 weeks.

Longitudinal trends for cohort: During the observation period, 43\% (9032/21212) of A and B priority applicants were housed compared with $17 \%$ (2738/16269) of C and D priority applicants. The majority ( $61.6 \%$ ) of applicants who became tenants decrease their level of
household crowding in the process. This was an average decrease of 1.45 people per bedroom (from 2.64 people per bedroom as applicants, to 1.19 people per bedroom as tenants).

Quality of data matching: The overall match rate over this 26 -month period was $92 \%$. Electronic matching achieved $65 \%$ with the remaining $37 \%$ by manual matching. The matching rate was slightly higher for housing tenants (92.5\%) compared with housing applicants $(91.2 \%)$ and for those aged $30-69$ years and Europeans. As well as the $8 \%$ of unmatched cohort members, a further $7 \%$ had to be excluded because their time in the cohort could not be accurately assigned.

Analysis of hospitalisations: This analysis confirmed that a considerable proportion (11\%) of hospitalisations represent 'administrative' events and overseas visitors and can be filtered out. A large group are also of low relevance to this research, notably 'waiting list' cases ( $16 \%$ ) and 'irrelevant conditions' ( $32 \%$ ). A further $5 \%$ can be excluded as probable readmissions for the same disease episode. This leaves $50 \%$ of 'standard filtered' hospitalisation data which can provide the numerator for the subsequent analyses. Applicants spent a mean of 229 days and tenants 638 days as part of the cohort during the 26 months ( 792 days) observation period (May 2003 to June 2005). These person-days provided the denominator for the analysis.

Hospitalisation rates for cohort population: The analysis of hospitalisation data identified a number of important characteristics of the cohort populations:

- Housing applicants and housing tenants have very high rates of recorded contact with the hospital system. These events are equivalent to 399/1000/year for housing applicants and 348/1000 for housing tenants, compared with 218/1000 for the other NZ population.
- The standard filter (excludes overseas visitors, non-hospitalisations, waiting list admissions, irrelevant conditions and one-month readmissions) removes $50 \%$ of recorded hospital contacts. After this filter is applied, hospitalisations remain markedly higher for the housing applicants $(223 / 1000)$ and housing tenants $(210 / 1000)$ compared with the other $N Z$ population (127/1000).
- The cohort population have significantly higher hospitalisations rates than the other NZ population for all age groups, and for males and females. They also have higher rates for European, Maori, and Pacific people.
- Surprisingly, hospitalisation rates were significantly higher for the highest income quintile of housing applicants, whereas there was a slight negative gradient for housing tenants with higher income associated with a lower hospitalisation rate. Similarly, there was a modest increase in hospitalisation rates for housing tenants living in the most deprived neighbourhoods where these properties are concentrated ( $42 \%$ are in NZDep 2001 category 10).
- There are significant differences in hospitalisation rates between HNZC regions. HNZC properties are disproportionately located in urban areas compared with rural areas. Hospitalisations rates are lower for those in satellite urban areas, and non-significantly higher in rural areas. Hospitalisations follow a familiar seasonal pattern with higher rates in winter, particularly for housing applicants.
- Age-standardised rates for the cohort population in total (housing applicants and tenants), compared with the other $N Z$ population, were significantly elevated for every disease grouping except for congenital diseases. Such differences were largest for endocrine, nutritional and metabolic diseases, mental and behavioural conditions, respiratory diseases, and skin and subcutaneous diseases.
- Age-standardised rates for the cohort population were also elevated for virtually every specific disease included in the analysis. Specific examples where rates were elevated two
fold or more included: Infectious diseases (tuberculosis, meningococcal disease, septicaemia, all forms of viral hepatitis); Respiratory diseases (pneumonia, bronchitis, chronic obstructive pulmonary disease, other lower respiratory infections, asthma); Skin and bone infections (impetigo, cutaneous abscess, cellulitis, lymphadenitis, osteomyelitis); Other diseases with an infectious origin (acute rheumatic fever, acute and unspecified nephritis syndrome); Cardiovascular diseases (hypertensive diseases, heart failure); Injuries (from contact with heat, assault, pedestrian injuries, dog bites, sharp glass); and Mental and behavioural disorders (most categories, plus intentional self-harm).
- Potentially avoidable hospitalisations were almost twice as high in the cohort population compared with the other NZ population, with injuries and poisonings about $35 \%$ higher.

## Hospitalisation rates for housing applicants compared with housing tenants:

- Housing applicants and housing tenants generally had similar rates of hospitalisation for most groups of diseases and specific diseases. However, housing applicants had significant higher rates of hospitalisation for some diseases: Respiratory diseases (notably acute pharyngitis, acute bronchitis, acute bronchiolitis and asthma); Mental and behavioural disorders (particularly mood disorders, neurotic and stress related disorders, mental disorders due to psychoactive substance use, plus intentional self harm,); and certain injuries (notably poisonings and toxic effects)
- Housing applicants had lower hospitalisation rates for some conditions, notably some skin infections (abscess, furuncle and carbuncle)
- Carrying out the analysis using age-ethnicity standardised rates removed some of the effects that were related to the different ethnic composition of the housing applicant and housing tenant populations compared with the other $N Z$ population.
- The use of age-ethnicity-standardised results reduced the rate ratio different between the cohort population and the other $N Z$ population by about $30 \%$ suggesting that some of this difference could be explained by the relatively high proportion of Maori and Pacific people in the cohort population. Even with this additional adjustment, housing applicants and housing tenants continued to experience significantly higher hospitalisation rates than the other $N Z$ population for all major disease categories except congenital diseases. For some specific diseases, this form of standardisation reduced the difference to non-significance, notably meningococcal disease, acute bronchitis, and malignant neoplasms of the stomach. For a minority of diseases, this standardisation resulted in an increase in rates.
- Age-ethnicity-standardisation also increased the hospitalisation rate in the housing applicants compared with the housing tenant populations (from RR 1.06 to 1.10 ) which is understandable, given the higher proportion of Pacific people who are housing tenants compared with the housing applicant population. This standardisation resulted in rates becoming significantly higher for housing applicants in some disease categories, particularly infectious and parasitic diseases and respiratory diseases. This standardisation resulted in rates becoming significantly higher for housing applicants for several specific diseases, including viral infection of unspecified site, other chronic obstructive pulmonary disease, and burns and corrosions.
- Restricting the definition of hospitalisation to overnight hospitalisation removed about $25 \%$ of events that involved attending as a day case. This restriction had little effect on the findings.

## Hospitalisation rates in relation to duration of tenancy:

- A better indication of the health effects of social housing can be obtained by comparing hospitalisation rates in the sub-group of applicants who subsequently became tenants, compared with tenants during their first year of hospitalisation. These populations had
exactly the same overall hospitalisation rates (rate ratio 1.00 , $95 \%$ CI $0.93,1.07$ ). This finding suggests no immediate health effects are associated with the move from waiting list to tenant. However, this finding will be investigated more fully in the future using longitudinal analysis. These populations had very similar rates of hospitalisation for major disease categories and specific diseases. The only differences were that hospitalisations for nervous system conditions were significantly more common among housing applicants. Acute bronchiolitis had markedly higher rates among housing applicants. Hospitalisations were significantly lower for cutaneous abscess, furuncle and carbuncle among the housing applicants.
- Extending this analysis, it is also useful to look at hospitalisation rates according to duration of tenancy. This analysis shows that hospitalisation rates are highest among housing tenants during their first year as tenants (277 per 1,000 per year). Hospitalisation rates decline over the subsequent 1-3 years as tenants, and then reach a plateau for those who are tenants for 4 or more years (about 182 per 1,000 per years). This hospitalisation rate remains significantly higher than that seen for the other $N Z$ population (about 127 per 1,000 per year). The pattern seen for major disease categories is broadly similar, with a decline from highest rates as housing tenants during the first year of the tenancy to lower rates with longer periods spent as HNZC tenants. The only exceptions are neoplasms and congenital conditions where rates remain relatively constant with duration of tenancy. The pattern seen for selected diseases is more mixed. Some diseases have a very pronounced decline in hospitalisation rates with duration of tenancy. This is particularly the case with mental health conditions, intentional self-harm, assault, and poisonings and toxic effects (some of which will be self-inflicted). Several of the infectious diseases also show a decline in hospitalisation rates with duration of tenancy. This decline is most marked for the intestinal infectious diseases, acute bronchiolitis, and chronic obstructive pulmonary disease. It is also evident for asthma.

Hospitalisation rates in relation to HNZC prioritisation: This analysis also reviewed the health outcomes associated with the HNZC prioritisation system, which distinguished higher priority housing applicants ( $\mathrm{A}+\mathrm{B}$ ) from lower priority housing applicants $(\mathrm{C}+\mathrm{D})$. This analysis shows that the population prioritised for social housing has a $44 \%$ higher hospitalisation rate ( 266 per 1000 per year) compared with those assigned a lower priority ( 185 per 1000 per year). However, even the lower priority applicants have a markedly higher hospitalisation rate than the other $N Z$ population (about 127 per 1,000 per year).

Hospitalisation rates in relation to household crowding level: This report includes a preliminary analysis of hospitalisation rates in relation to household crowding level of housing applicants and housing tenants. To simplify the analysis, each cohort participant was assigned the crowding level recorded in their most recent NA or IRR. Because levels of household crowding are already known to be highly associated with ethnicity, this analysis used ageethnicity standardised rates. This analysis showed the following:

- For housing applicants, hospitalisation rates were similar for those classified as crowded as for those who were uncrowded.
- For housing tenants, hospitalisation rates were significantly higher for those classified as crowded, and considerably elevated for those with a 2 or more bedroom deficit (RR 1.19, $95 \%$ CI 1.14, 1.26).
- For combined housing applicants and housing tenants, hospitalisation rates were significantly elevated for those classified as crowded for several major disease categories, particularly neoplasms, musculoskeletal and connective tissue diseases and skin and
subcutaneous diseases. Conversely, hospitalisation rates for crowded households were significantly less than for uncrowded households for mental and behavioural disorders.
- For specific diseases, hospitalisation rates were significantly elevated in those households classified as crowded for some infectious diseases, including bacterial infection of unspecified site, shingles (zoster), acute bronchiolitis and most forms of skin infection (cutaneous abscess, furuncle and carbuncle, other local infection of skin and subcutaneous tissue, and osteomyelitis). Of note were the significantly higher rates for acute myocardial infarction and heart failure. Injuries to wrist and hand and injuries to hip and thigh were all significantly more common causes of hospitalisation in crowded households. External causes that were also significantly more common were falls and exposure to inanimate mechanical forces. Interestingly, hospitalisations for mental disorders due to psychoactive substance use and manic episode or bipolar disorder were significantly less common in crowded households, whereas the opposite pattern was seen for admissions diagnoses as adult personality disorders.

Hospitalisation rates for active smoking adults and children in smoking households: This report includes a preliminary analysis of hospitalisation rates in relation to active and passive smoking.

- Smoking data was reported by $69.1 \%$ of tenants $>19$ years. This group had significantly higher hospitalisation rates than non-smokers. Age-standardised hospitalisation rates were significantly elevated for neoplasms, respiratory diseases, skin and subcutaneous diseases, mental and behavioural disorders and external causes. Using age-ethnicity standardised rates, the association with smoking was less marked, and only persisted for neoplasms, mental and behavioural disorders and injuries and poisonings. Conversely, age standardised and age-ethnicity standardised hospitalisation rates for smokers were significantly less than for non-smokers for infectious and parasitic diseases, diseases of the eye and adnexa, and diseases of the circulatory system. For specific diseases, agestandardised and age-ethnicity standardised hospitalisations rates were significantly elevated for acute tonsillitis, chronic obstructive pulmonary disease, cutaneous abscess, furuncle and carbuncle, most groups of mental and behavioural disorders, poisonings and toxic effects, fracture to wrist and hand, intentional self harm and assault.
- The smoking status of households was reported for $42.1 \%$ of tenant children $<15$ years. Overall age-standardised and age-ethnicity standardised hospitalisation rates were not significantly elevated for children in smoking compared with non-smoking households. Age-standardised and age-ethnicity standardised hospitalisation rates were significantly elevated for children in smoking households compared with non-smoking households for diseases of the blood and immune system and musculoskeletal and connective disorders. For specific diseases, hospitalisations rates were significantly elevated for cellulitis and some specific injuries.

## Discussion

The 29 months operation of the Housing Crowding and Health Study has demonstrated that the study is technically feasible and likely to be able to investigate all of its planned objectives. In particular:

- HNZC administrative data can be successfully transferred via NZHIS in a form that enables detailed analysis of the characteristics of individuals and households.
- Most $(91.7 \%)$ applicants and tenants can be matched to their NHI number, which is the key to linking to hospitalisation records.
- New and modified questions on the NA and IRR forms are being successfully completed in the majority of cases.
- Applicants are exposed to significantly higher levels of household crowding than tenants, who are in turn living in more crowded conditions than the New Zealand population generally. Crowding levels are particularly high for housing applicants sharing houses with non-applicant households.
- The majority ( $61.6 \%$ ) of applicants who become tenants decrease their level of household crowding in the process, and this decrease is marked.

This analysis also provides useful information on the health status of housing applicants and housing tenants:

- Housing applicants and housing tenants have relatively high rates of recorded contacts with the hospital system overall and for virtually every major disease grouping compared with other New Zealanders. These findings have implications for the effective delivery of health services to this population.
- This population also has high rates of hospitalisation for many groups of diseases that are at least partly preventable (e.g. most forms of infectious disease). This observation suggests that there could be health gain for this population, and possibly also efficiency gains for the health system, by use of a range of prevention measures.
- Some of the diseases with particularly high rates in this population have well defined environmental causes (e.g. asthma, injuries), which suggests the potential for specific prevention programmes.
- The initial analysis of the role of household crowding supports continuing efforts by HNZC to reduce levels of household crowding in its properties.

These findings need to be interpreted with considerable caution for a number of reasons:

- Limitations with the numerator - Hospitalisations will only capture a proportion of all diseases cases. For severe diseases, such as meningococcal disease, this proportion will be high, but for less severe diseases, such as mumps, this proportion will be low and possibly biased.
- Limitations with the denominator - Accurately assigning participants (and their persontime) to the study is prone to a number of sources of error. Some of these errors reflect the limitations of using administrative data which is collected for applicant and tenant management purposes.
- Confounding - The analysis of hospitalisation data uses age-standardised rates to manage confounding by age. However, there are other confounders that have not yet been considered in the analysis (e.g. tobacco smoke exposure). There are also other unmeasured confounders that cannot be included in the analysis (e.g. there are probably unmeasured differences between tenants living in HNZC houses for $<1$ year compared with those who stay longer).
- Study size - Some of the diseases reported here are still relatively uncommon so findings need to be interpreted with caution. This limitation will diminish with time as the cohort size increases.
- Causal inference - This analysis treats the cohort as three cross-sections (housing applicants, housing tenants, and other NZ). The finding that some diseases have higher rates in one or other of these populations does not necessarily imply a causal association. For some conditions 'reverse' causality is operating in that those with some chronic diseases seek and are prioritised to receive social housing (e.g. multiple sclerosis). Future analyses will exploit the longitudinal nature of this cohort study to try to answer questions
about whether a change in housing status is associated with a change in health status. Such analyses have much greater potential to answer such causal questions and will be the key analyses of this study.

The next stage of the analysis will investigate the role of household crowding using multivariable methods and also the contribution of environmental tobacco smoke. It will also use longitudinal analysis to assess the effects of a change in household crowding level over time.

Table 1.1: Summary of characteristics of housing applicant and tenant households at 30th June 2005, compared to New Zealand population (2001 census)

| Characteristic | Housing <br> applicants $^{1}$ | Housing <br> tenants $^{2}$ | NZ <br> Population $^{3}$ |
| :--- | :---: | :---: | :---: |
| Population | 9976 | 61118 | 1344000 |
| Number of households | 26484 | 197794 | 3630000 |
| Number of people | 73 weeks |  |  |
| Average duration in current situation | 50 weeks |  |  |
| Average duration on waiting list for |  | 387 weeks | - |
| current applicants |  |  |  |
| Average duration in tenancy |  |  |  |
| Demographic and SE characteristics | 25.1 | 27.9 | 34.9 |
| Age and sex | 57.4 | 54.8 | 51.2 |
| Average age |  |  |  |
| Female \% | 25.1 | 23.8 | 85.5 |
| Ethnicity | 33.5 | 35.3 | 15.0 |
| European \% | 26.7 | 35.1 | 5.2 |
| Maori \% | 8.9 | 3.1 | 6.2 |
| Pacific \% | 10.7 | 4.4 | 0.8 |
| Asian \% | 2.1 | 7.2 | -- |
| Other \% | 42.7 | 35.5 | 12.3 |
| Not Stated \% |  |  |  |
| One parent with children \% | 268.33 | 279.70 | 873.67 |
| Household income | 78.7 | 91.1 | 24.5 |
| Average weekly income |  |  |  |
| Receipt of income from Gov. benefit \% | -- | 44.5 | 32.9 |
| Smoking status |  | 31.9 | 24.0 |
| Smoker in household \% | -- |  |  |
| Proportion of adults who smoke \% |  |  | 2.2 |
| Crowding levels | 4.0 | 3.2 | 2.7 |
| Sharing with another family \% | 2.4 | 2.5 | 3.1 |
| Average number of people in household | 1.7 | 1.2 | 0.9 |
| Average number of bedrooms | 46.1 | 23.6 | 5.1 |
| Average people per bedroom | 25.4 | 7.3 | 1.2 |
| Short of 1 or more bedrooms \% |  |  |  |
| Short of 2 or more bedrooms \% |  |  |  |

Notes:
${ }^{1}$ Housing applicants are those who have been "confirmed" and placed on the waiting list for a house
${ }^{2}$ Housing tenants are those who complete an IRR. This excludes 1750 HNZC tenant households not claiming this benefit (i.e. who are paying market rent).
${ }^{3}$ Based on 2001 NZ Census. Totals include HNZC applicants and tenants. Sources: Statistics New Zealand. What is the extent of crowding in New Zealand? Wellington: Statistics New Zealand, 2003.
${ }_{5}^{4}$ Income has been adjusted using the Jensen Equivalised Annual Household Income formula
${ }^{5}$ Smoking status for the NZ population is based on 1996 census

## 2 Introduction

## Origin of the study

This study was set up following the meningococcal disease case-control study which showed that household crowding was the strongest risk factor for meningococcal disease in Auckland children.[1] Other New Zealand work has also shown that rates of some infectious diseases are higher for people living in suburbs with a higher proportion of crowded homes.[2] Despite this evidence, some New Zealand commentators consider that "The debate about the relationship between crowding and health is long standing and inconclusive".[3] In addition, there are no published studies on the impact of reductions in household crowding on disease risk.[4] This present study aims to fill these evidence gaps.

## Aims of the study

1. To assess the relationship between levels of household crowding and rates of hospitalisation for infectious diseases in a cohort of New Zealand households.
2. To assess the impact of a reduction in household crowding on the risk of infectious disease in this cohort of households.
3. To assess the impact of household crowding and environmental tobacco smoke on respiratory diseases and other health outcomes.

## Aims of this report

The first aim of this report is to describe progress with constructing the cohort and measuring health outcomes using linked hospitalisation data. This process depends on linking applicants and tenants to their hospital records and calculating their person time in the cohort and rates of hospitalisation generally and for specific diseases.

Secondly, this report aims to provide a more comprehensive description of the characteristics of the cohort members and additional information on their health status. The work summarised in this report aims to update the interim report produced in 2004. ${ }^{1}$ That report showed that it was technically feasible to establish a well-defined study population using administrative data collected by HNZC. That report presented the cross-sectional characteristics of this population, such as age, sex, ethnicity, income, crowding levels and smoking status. It also examines longitudinal aspects of this cohort and how households move in and out of applicant and tenant states over time. This present report updates the interim analysis by including an analysis of the first 26 months of matched hospitalisation data. A further aim of this report is to provide our major partner, Housing New Zealand Corporation, with an overview of some of the health issues affecting their client population.

[^0]
## Model of housing influences on health outcomes

This study is seeking to investigate the health effects of key 'contextual' housing factors in terms of their contribution to health outcomes. In doing this, the analysis needs to consider 'compositional' aspects of the population which also affect health outcomes. These variables, or 'covariates' are summarise in the table below (Table 2.1) using the levels that He Kainga Oranga has adopted for classifying factors in the built environment that contribute to health.

The initial analysis will consider these variables in a cross-sectional manner. It will then proceed to calculate rates for sub-populations of the cohort population who have been stratified according to these variables (notably for type and duration of tenure and crowding level). The analysis will then develop a multivariate model and apply longitudinal data analysis to assess the contribution of these variables. This model will need to take account of the fact that some of these variables change over time. Some of these contextual housing variables are amenable to change (such as household crowding and tenure) so it is particularly important to assess their independent contribution to health outcomes.

Table 2.1: Classification of factors affecting the health of HNZC applicants and tenants and their measurement as part of the Housing, Crowding and Health Study

| Level | Factors | Variable measured (Covariate) |
| :--- | :--- | :--- |
| Region, <br> Neighbourhood <br> and Community | Quality of local <br>  <br> access to services | HNZC region will be included in model <br> DHB and/or neighbourhood could potentially be <br> included |
| House <br> (physical) | Quality of housing, <br> including safety, <br> warmth and dryness | No measure available though composite value <br> could potentially be generated from RENTEL data <br> in future |
| Household | Household crowding <br> level | Range of measures will be calculated including <br> household occupancy, bedroom deficit |
|  | Type of tenure and <br> duration of tenancy | Housing applicant or tenant <br> Duration of tenancy (<1 year, 1-3 years, etc) |
|  | Household income | Equivalised household income (but uniformly low <br> compared with NZ population) |
| Individual | Passive smoke <br> exposure | Assigned based on voluntary smoking question Age |
|  | Date of birth allows age to be calculated at any <br> point in time for longitudinal analysis |  |
|  | Sex | Recorded |
|  | Established chronic <br> disease and disability | Recorded <br> Not specifically measured for individual (but likely <br>  <br> allocation system) |
|  | Active smoking | Not specifically measured for individuals (but <br> assumed to be low based on the HNZC social <br> allocation system) |
|  | Voluntary reporting by housing tenants |  |
|  |  |  |

## 3 Methods

### 3.1 Data Collection

This study is based on collaboration with Housing New Zealand Corporation (HNZC), which is the largest provider of social housing in New Zealand. HNZC manages approximately 66,000 tenancies and each year assesses and places about 16,000 households on a waiting list for social housing. Its operational structure is organised into 11 regions and 46 neighbourhood units. Table 3.1 lists the HNZC regions and the number of area offices and properties in each.

Table 3.1: HNZC regional office structure, 2005

| Region | Neighbourhood Units <br> (No.) | Properties <br> (No.) |
| :--- | :---: | :---: |
| Bay of Plenty | 3 | 2,687 |
| Central Auckland | 5 | 9,365 |
| Chch/Nelson/Marlborough | 5 | 6,702 |
| East Cape/Hawkes Bay | 3 | 4,323 |
| Manawatu/Taranaki/Wairarapa | 4 | 4,419 |
| Northland | 1 | 2,063 |
| South Auckland | 6 | 13,360 |
| Southern | 4 | 3,248 |
| Waikato/Coromandel/King Country | 4 | 4,115 |
| Wellington/Hutt Valley | 6 | 8,718 |
| West \& North Auckland | 5 | 6,001 |
| Community Group Housing | N/A | 1,521 |
| Total | 46 | 66,522 |

In the process of allocating and managing these properties, HNZC collects information about these applicants and tenants. Figure 3.1 shows diagrammatically the movement of applicants and tenants. The first main point where information is collected is the Needs Assessment (NA) interview when applicants apply for a house and their housing need is assessed according to current housing policy. The second main point is when the tenant applies for an Income Related Rent (IRR) usually a year after the tenancy begins unless a change of circumstance occurs. An initial IRR form is effectively filled out by HNZC when an applicant is first allocated to a house. After that, the IRR is filled out as a self completed form each year. In addition, applicants on the waiting list and tenants are required to provide information to HNZC if their circumstances change.

The Needs Assessment information is collected via a semi-structured interview so fields are likely to be completed if the Housing Support Manager asks all the questions or prompts for an answer for each question.

The IRR is self-reported so missing values occur more regularly on the fields that are not mandatory for the calculation of the IRR. In addition, the field on smoking behaviour is specifically identified as voluntary.

Information is obtained from households about their circumstances at several key points:

- Applicant Needs Assessment interview
- Applicant change of circumstances
- Tenant annual Income Related Rent application
- Tenant change of circumstances

There are also 'observations' that record applicant and tenant moves

- Applicant exits the waiting list
- Applicant becomes a tenant
- Tenant exits the HNZC tenancy
- Tenant property change

Figure 3.1: Flow of people between the other $N Z$ population and housing applicant and housing tenant populations

Information on the NA and IRR forms is entered into the HNZC database (RENTEL). The HNZC staff member enters the NA information after the interview or at the end of the day. Housing managers enter the IRR data when the IRR forms are received from tenants. Particular questions that are important for HNZC, whether for the assessment of need or the
calculation of income related rent, are mandatory in RENTEL and should always be completed. RENTEL will not allow the entry process to continue until these have been completed.

The HNZC RENTEL database also includes detailed information about their housing stock, notably the number of bedrooms in each house. These data are linked to tenants' records and in turn to the IRR databases.

### 3.2 Data transfer and linking to hospitalisation records

HNZC applicant and tenant information collected each month is transferred to the New Zealand Health Information Service (NZHIS) for matching to the National Health Index (NHI). The data arrives at NZHIS in monthly batches of IRR and NA records for the preceding month and is in a series of linked tables that are mainly tenancy based. An encrypted version of the NHI is subsequent used by the Wellington School of Medicine and Health Sciences (WSM\&HS) researchers to identify any hospitalisations recorded for members of the cohort that occurred during the study period.

Figure 3.2 Steps involved in the transfer of housing tenant and applicant data from HNZC to WSM, including its linking to hospitalisation data by NZHIS

This process of identifying the NHI number for applicants and tenants uses electronic followed by manual matching. Electronic matching is based on the following fields: family name, first name, date of birth, and sex. Manual matching is based on looking for close matches for each unmatched record.

The confidentiality of study participants is fully protected. NZHIS strips names from the file after the NHI matching process. The NHI is replaced by an 'encrypted NHI' making the data completely anonymous. This files of NZHIS data with attached encrypted NHIs is then transferred to WSM\&HS for analysis.

Researchers at WSM\&HS use this encrypted NHI to track members of the cohort and link them to hospitalisations that occurred during the study period. NZHIS has separately supplied the researchers with a copy of National Minimum Dataset (NMDS). This dataset includes all hospital admissions reported by New Zealand's district health boards (DHB) with all entries including their encrypted NHI. The researchers use this file to identify hospitalisations in the cohort population that have occurred over the study period. They can also identify hospitalisations for those New Zealanders who are not in the cohort population, which allows the calculation of comparison rates.

### 3.3 Data analysis

The data for this analysis were collected over the period February 2003 to June 2005. The data analysis was conducted in SAS (SAS(R) Proprietary Release, Version 9.1).

### 3.3.1 Construction of applicant and tenant cross-section

The main description of the cohort population is based on a cross-section of data. This set of data is accumulated over time as people fill out an IRR or NA form and change their circumstances in other ways. Thus one would expect that after a year most of the tenants would be in the dataset (that is, those who fill out IRRs, which require annual renewal). The cross-section is chosen at the end of the data series so as to accumulate as many people as possible. The cross-section contains the last known record for the household and any vacated tenancies are removed. This way it is a snap shot of the population at the chosen date (in this case the 30 June 2005).

The data sets contain an inherent uncertainty in tracking people and tenancies. If the reference numbers (both for individuals and households) change for various reasons it is impossible to track the individuals/tenancies over time, without identifying information. This problem is largely resolved by linking individuals to their unique NHI number.

### 3.3.2 Key variables

## Ethnicity

The analyses presented in this report use three sources of ethnicity data:

- HNZC tenancy data - HNZC now uses the standard Census question for recording ethnicity. This information is obtained by interview for housing applicants (via the Need Assessment form) and by self-completed questionnaire for tenants (via the IRR form).
- NZHIS hospital discharge data, based on details recorded on the NHI. This information is obtained from contacts with the health service (usually hospitals) during which NHI information is recorded and updated.
- Census data - Ethnicity information obtained from the 2001 Census.

To be comparable to the Census data the "New Zealander" field is coded as New Zealand European. Multiple ethnicities are allowed so two classifications have been used for ethnicity. The first is "Exclusive" coding which is also called prioritised exclusive coding. In this classification scheme only one ethnicity is allowed and is prioritised firstly for Maori, then for Pacific, Asian, New Zealand European, and Other. The inclusive coding scheme allows for multiple ethnicities so is more representative of the data. However this means that the ethnicities add to more than $100 \%$ as people can have multiple ethnicities.

## Equivalised household income

The sum of income field measures total weekly household income that is relevant to the calculation of the income- related rent. Jensen (1988) equivalised income weights are used to adjust for household size and composition (adults and children). The household income is adjusted by dividing the weekly income by the appropriate weight from Table 3.2 for the number of adults and children in a household. If there are more than 4 adults or 6 children then the value of 2.44 is used. If there are no adults (people aged 18 or more) but there are independent youths on a benefit in the household then the number of adults is set to one and the number of children decreased by one.

Table 3.2: The revised Jensen Index

| Number | Number of children |  |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Of adults | 0 | 1 | 2 | 3 | 4 | 5 | 6 |  |
| 1 | 0.65 | 0.91 | 1.14 | 1.34 | 1.52 | 1.69 | 1.85 |  |
| 2 | 1.00 | 1.21 | 1.41 | 1.58 | 1.75 | 1.91 | 2.06 |  |
| 3 | 1.29 | 1.47 | 1.65 | 1.81 | 1.96 | 2.11 | 2.25 |  |
| 4 | 1.54 | 1.71 | 1.87 | 2.02 | 2.16 | 2.30 | 2.44 |  |

Based on Jensen 1988 [5]

### 3.3.3 Crowding Measures

Three crowding measures are used in this report namely household size, people per bedroom and the Canadian National Occupancy Standard (CNOS). These measures use two key variables, number of people in the household and the number of bedrooms in the house.

The number of bedrooms in the tenant households is recorded in the property database. There are a number of different variables that measure the bedrooms in the applicant household. HNZC in the past has recorded the number of bedrooms that the applicant household has access to and has used this to measure the crowding levels to assess the need for housing. As a result of the HC\&HS, some additional fields have been added to the NA form to record the total number of bedrooms in the house and the number of other rooms (such as the lounge) that are being used as bedrooms. To calculate the number of bedrooms in the applicant house the
above variables have been incorporated in the following manner. If the "total bedrooms" is zero, then the "current bedrooms" is used instead, if the current number of bedrooms is also zero then the "other rooms used" is used instead.

## Crowding Levels Measured by People Per Bedroom

One measure of crowding is to calculate the number of people per bedroom. A value more than 2 is considered crowded as it is generally accepted that there should not be more than 2 people per bedroom. Some households will be crowded at levels between 1 and 2 people per bedroom depending on the mix of occupants.

Two different methods were used to calculate the crowding levels for the applicants as follows:

1. People per bedroom $=\quad \frac{\text { Total non-applicants }+ \text { Total applicants }}{\text { Total Bedrooms }}$
2. People per available bedroom $=\underset{\text { Bedrooms applicants have Access to }}{\text { Total applicants }}$

This second method is the one that HNZC currently uses to measure crowding levels for applicants. As the formula shows, this method attempts to eliminate the effect of nonapplicants (where an applicant household is sharing a house with a non-applicant household) by removing them from both the numerator and denominator.

## Canadian National Occupancy Standard

The Canadian National Occupancy Standard (CNOS)[6] measures the bedroom deficit by calculating the number of bedrooms needed for the household and comparing this to the number of bedrooms available. This gives the degree of bedroom deficit for crowded households. This method has been widely used in New Zealand to assess levels of household crowding [7]. The standard sets the bedroom requirements of a household using the following composition criteria:

1. There should be no more than two people per bedroom.
2. Parents or couples share a bedroom.
3. Children under five years, either of the same or opposite sex, may reasonably share a bedroom.
4. Children under 18 years of the same sex may reasonably share a bedroom.
5. A child aged five to 17 years should not share a bedroom with one under five of the opposite sex.
6. Adult 18 years and over and any unpaired children require a separate bedroom.

### 3.3.4 Analysis of hospitalisation data

This report includes an analysis of hospitalisation data obtained for the 26-month period May 2003 to June 2005.

The matching process to identify hospitalisations in the cohort population has been described above (section 3.2). The remainder of this section describes the steps involved in analysing this set of HNZC applicant and tenant data with their linked hospitalisation records.

This project uses hospitalisation data as a way of measuring health outcomes. The starting point is the NZHIS National Minimum Dataset (NMDS). This dataset includes all hospital admissions reported by New Zealand's district health boards (DHB). The analysis and interpretation of hospitalisations data has several steps, each of which requires decisions that affect the resulting analysis. These steps are summarised in the following flow chart (Figure 3.3).

Figure 3.3 Steps involved in analysis of hospital discharge data
(NB. The order of some steps will not affect the end result)

## Obtain hospitalisation data

The source of hospitalisation data is the National Minimum Dataset (NMDS) which is"... a national collection of public and private hospital discharge information, including clinical information, for inpatients and day patients." [8] The NMDS is managed by NZHIS which provided a data dictionary [8] to describe the data held in this collection. Several of these fields are useful for classifying and filtering events for analysis.

Clinical code

- The clinical description of a condition, injury or underlying cause of death or procedure performed. These codes are based on those specified in the international classification of diseases and related health problems, $10^{\text {th }}$ Revision Australian Modification (ICD-10-AM). These codes are organised into a series of tables, including the following:
- Clinical code type A Principal diagnosis
- Clinical code type B other relevant diagnosis
- Clinical code type E external cause of injury
- Clinical code type O operation/procedure

Injury events get A, B and E codes. They also have additional place of occurrence and activity codes depending on the type of E code that has been assigned.

DRG code

- Codes based on a combination of diagnosis, age group, and procedure. There are currently 956 discrete codes. These codes are assigned to each health event by a DRG program and are meant to reflect clinically meaningful groups with similar resource consumption.

Event type

- Birth event (infants born in reporting hospitals)
- Intended day case
- Psychiatric inpatient event (include day patients)
- Non-psychiatric inpatient event (include day patients)

MDC codes

- Major diagnostic category assigned by DRG group programme (23 codes based on chapters used in ICD.9)

The NMDS also contains other codes that describe the sources of admission and health specialty providing the care. This information helps in understanding the purpose of the admission and potentially allows filtering of events that are not of interest.

Admission source code

- Routine
- Transferred

Admission type code

- Acute admission (AC)- an unplanned admission on the day of presentation at the healthcare facility (includes retired code ZC for acute ACC covered).
- Arranged admission (AA)- planned admission <7days after decision was made that the admission was necessary (includes retired code of ZC for arranged admission, ACC covered)
- Waiting list (WN)- planned admission 7+ days after decision was made that the admission was necessary (includes retired code of ZP for waiting list ACC covered), Elective admission to a private hospital
- Other admission includes elective admission of privately funded patient (AP) and psychiatric patient returning from leave>10 days (RL) (and retired code of ZP for Waiting list, ACC covered)

## Health specialty code

- Codes that classify specialty based on service and qualifications of health professional providing the service.

## Remove non-hospitalisations and overseas visitors

Some of the events in the NMDS have been entered for administrative reasons and so need to be removed e.g. transfers, boarders. Some represent non-hospitalisations, almost by definition e.g. cancelled operations, error DRGs. There are also some inconsistencies between DHB in what they record as a hospitalisation e.g. well babies are recorded by some DHB and not others. Overseas visitors are also generally removed, as they are not included in the New Zealand denominator population used for calculating disease rates. These events are removed using a set of filters, many of which have been adapted from those used by the Ministry of Health in analysing hospital throughput data.[9] The following filters are applied:

- Transfers - Patients may be transferred between hospitals as part of treating the same disease episode. This analysis removes events where the admission source code indicates a transfer.
- Boarders - People may be admitted for reasons other than treatment, e.g. parents accompanying children. Boarders are identified by having a primary diagnostic code in the range Z763-Z764.
- Cancelled operations - Non-acute admissions with ICD code indicating procedure not carried out (Z53)
- Well babies - Some DHB routinely admit newborn well babies and some do not. These events are excluded where the primary diagnostic code is Z38.
- Error DRGs - Events coded to an error DRG are excluded (960Z, 961Z, 962Z, 963Z).
- Overseas patients - Those patients with "N" recorded in the "NZ_RES" field of the NMDS.

## Select admission type(s)

The population of events recorded as hospital discharges includes a diverse range of health events some of which provide poor indicators of disease episodes in the population e.g. elective surgery cases admitted from the waiting list. DHBs also vary in their recording practices. At the most fundamental level, even the definition of what constitutes a hospitalisation varies. Hospital "Admission" is defined as "The documentation process ... by which a person becomes resident in a healthcare facility. For the purpose of the national collections, healthcare users who attend for more than three hours should be admitted." [10] However, it is widely known that this rule is applied inconsistently.

To produce a more consistent and meaningful set of data, it is usually necessary to select admission types that are appropriate for the research questions being investigated. This can be done in two main ways:
Firstly, by using the recorded admission 'type'.

- Acute admission - defined as unplanned admission on the day of presentation at the healthcare facility.
- Arranged admission - defined as planned admission $<7$ days after decision was made that the admission was necessary.
- Waiting list admissions - defined as planned admission 7+ days after decision was made that the admission was necessary.
Secondly, by classifying events by their duration and/or severity.
- Emergency Department cases - These are Emergency Department (ED) / Accident and Emergency (A\&E) attendees recorded as admissions.
- Over-night admissions - These are admissions that result in a hospital stay of one or more days.

As described in the results section, this present research is largely focussed on acute health events rather than elective procedures so will focus on acute and arranged admissions.

## Select whether to include only principal diagnosis

This project is concerned with identifying specific disease events in the cohort population we are following. These diseases will often be coded as the principal (first listed) diagnosis for an admission, but may also be listed as an additional diagnosis.

- Principal diagnosis is defined as: "The diagnosis established after study to be chiefly responsible for causing the patient's episode of care in hospital (or attendance at the healthcare facility). The phrase "after study" in the definition means evaluation of findings to establish the condition that was chiefly responsible for the episode of care. Findings evaluated may include information gained from the history of illness, any mental status evaluation, specialist consultations, physical examination, diagnostic tests or procedures, any surgical procedures, and any pathological or radiological examination. The condition established after study may or may not confirm the admitting diagnosis." $[10]$ This is the ICD. 10 code that appears in the first diagnostic field provided with each discharge record.
- Additional diagnosis is defined as: "A condition or complaint either co-existing with the principal diagnosis or arising during the episode of care or attendance at a healthcare facility. For coding purposes, additional diagnoses should be interpreted as conditions that affect patient management in terms of requiring any of the following: therapeutic treatment; diagnostic procedures; increased nursing care and/or monitoring." ${ }^{[10]}$ This is the ICD. 10 code that appears in any of the remaining 19 diagnostic fields provided with each discharge record.

The focus of this research project is mainly on conditions that will be recorded as the "principal diagnosis". However, some of these conditions may sometimes be recorded as additional diagnoses so there is potential to repeat these analyses based on the appearance of the ICD. 10 codes of interest as either the principal diagnosis or in any of the diagnostic fields.

## Select whether to allow repeat admissions

People may be admitted multiple times for the same condition, either as part of the same episode, or because of recurrences of the same condition. This project is generally concerned with identifying and counting each distinct disease episode. The NMDS data therefore need to be filtered to distinguish new health events from repeated admissions for the same illness episode. This step uses a decision rule that excludes subsequent admissions for the same person if they were discharged with the same diagnostic code within a defined period of the first admission. This analysis has been repeated to assess different combinations of filters.

- Based on ICD. 10 clinical code at 3 character level - Appearing either as the same principal diagnosis (narrow exclusion) or as same principal or additional diagnosis (wide exclusion)
- Based on different readmission periods - A single disease episode may last days to months so any time rule for identifying new disease episodes must be a balance between sensitivity and specificity. This analysis will explore a range of time intervals from 1 to 12 months.

## Select and remove irrelevant hospitalisations

A further filtering process is to select and remove types of hospital care that have little relationship to the research question being investigated. Commonly used groups are:

- 'Same day’ diagnostic procedures - Same day colposcopies, cystoscopies, ERCPs, colonoscopies, gastroscopies, bronchoscopies and overnight sleep apnoea testing.
- Same day treatment of chronic conditions - Renal dialysis, chemotherapy and radiotherapy, lithotripsy, blood transfusions
- Maternity care, which reflects demographic and reproductive, patterns in the population and healthcare policies - Those patients with a principal diagnosis in the ICD. 10 chapter for "Pregnancy, childbirth and the puerperium" (O00-O99).
- Perinatal care (up to the end of the first week of life), which again reflects demographic and reproductive patterns and hospital admissions practices - Those patients with a principal diagnosis in the ICD. 10 chapter for "certain conditions originating in the perinatal period" (P00-P96).
- Disability support service (DSS) admissions - Where there is an indication the person was admitted for respite care (based on having a Disability Support Services health specialty code, a Rehab DRG ('Z60A', 'Z60B', 'Z60C'), Respite care primary diagnosis code ('Z742', 'Z755'), Admission in DSS institutions and no operation or procedure performed).

## Select conditions of interest

This project is using hospitalisation data as a way of measuring health outcomes, particularly those that are plausibly related to housing conditions. It is therefore necessary to specify the range of conditions that are of interest. This analysis considers hospitalisations for the following categories of diagnoses:

- Broad diagnostic groups - Classified according to ICD. 10 chapters.
- Specific diseases - Classified according to specified ICD. 10 codes at the 3-character level.
- Specific diseases with a known link to crowding, including infectious diseases, respiratory infections and asthma, skin and bone infections, other diseases with infectious causes
- Other diseases where housing conditions may be important, including cardiovascular diseases and mental and behavioural disorders
- Injuries and poisonings and their associated external causes. These conditions can be selectively filtered to include only those with a place of occurrence coded as "home."
- Specialised groups of diseases - These are collections of diseases with certain underlying common characteristics. Examples include Potentially Avoidable Hospitalisations (PAM). [11]. These are usually defined based on specified ICD. 10 codes.

## Calculate disease rates

Disease occurrence is generally measured by incidence rate which is usually expressed as cases per 100000 population per year. Much of the analysis is concerned with comparing rates between populations with different housing circumstances (e.g. applicants vs. tenants, more crowded households vs. less crowded households). These populations are invariably of different size, so it is necessary to compare rates, rather than numbers of cases.

Calculation of hospitalisation rates in this study requires correctly identifying hospitalisations that occur while subjects are either housing applicants or tenants (the numerator), and correctly counting time that they spend as applicants or tenants (the denominator). Comparison rates for the NZ population who are not in the cohort can be calculated by deducting these figures from the total NZ population.

Subjects can only be contributing to the study (i.e. recorded as having a hospitalisation or adding person time to the study denominator) while they are known to be a housing applicant or tenant. It is necessary to carefully assess whether the person can be correctly assigned to being in the study as an applicant or tenant.

This analysis used the following general rules:

- Subjects start contributing to the applicant population from the date of their Needs Assessment application to HNZC, plus time before that that they indicated they were living in this situation i.e. with this number of people in this house (up to a maximum of 12 months). They stop contributing as applicants as soon at they are recorded as exiting ie become a tenant or are removed from applicant list.
- For tenants, their time in the cohort study starts from either (i) For new tenants, from the date they became a tenants or (ii) For existing tenants at the start of the study period, from June 2003, plus up to 12 months prior to that date (ie June 2002) or less if they became a tenant during that period.
- This analysis also identified a proportion of individuals (based on encrypted NHI number) with overlapping time spend as applicants and tenants. These situations have sets of rules for their treatment, which are summarised in the results section (9.1.7).

This analysis of hospitalisations created the following variables:

- Applicant hospitalisations $=$ Hospitalisations occurring while an applicant
- Tenant hospitalisations $=$ Hospitalisations occurring while a tenant
- Other NZ hospitalisations = Total NZ hospitalisations - cohort hospitalisations (applicant hospitalisations + tenant hospitalisations)

To calculate the rate at which hospitalisations occur, it was also necessary to calculate the amount of time people spent in these three groups (denominators):

- Applicant days = Days spent as an applicant
- Tenant days = Days spent as a tenant
- Other NZ days = Total NZ days (based on census) - Cohort days (applicant days + tenant days)

| Applicant hospitalisation rate $=$ | $\frac{\text { Applicant hospitalisations x 100 000 }}{\text { Applicant days } / 365.3}$ |
| :--- | :--- |
| Tenant hospitalisation rate | $=\frac{\text { Tenant hospitalisations x } 100000}{\text { Tenant days } / 365.3}$ |
| Other $N Z$ hospitalisation rate | $=\frac{\text { Other } N \text { Z hospitalisations x } 100000}{\text { Other } N Z \text { days } / 365.3}$ |

These rates are expressed as hospitalisations per 100000 people per year, hence the multiplier of 100000 in the numerator and the divisor of 365.3 in the denominator to convert days to years.

## Calculate adjusted rates

Where populations are very different, particularly if they have different age structures, we expect their disease rates to be very different. This is because age is such a strong predictor of health. It is therefore common practice to convert "crude rates" to "age-standardised rates". This process effectively removes the confounding effects of age from the comparison. This process can be further extended to calculate age-ethnicity standardised rates. This standardisation can be justified on the basis that the ethnicity composition of the HNZC population is quite different to the total New Zealand population and ethnicity is a strong independent predictor of health.

Most analyses used in this report converts crude rates into age-adjusted rates by direct standardisation. Standardisation is to the age structure of the total New Zealand population at the time of the 2001 census. This standardisation uses the following age bands: 0-4, 5-9, 1019, 20-29, 30-39, 40-49, 50-59, 60-69, 70+.

For the age-ethnicity standardised rates, the age-ethnicity structure of the cohort population was used. This standardisation used age groups in 10 -year bands up to 69 years, then $70+$. Ethnicity was divided into 5 groups used prioritised ethnicity: Maori, Pacific, Asian and Other, European, Not Stated.

Confidence intervals for standardised rates are calculated using the method described by Rothman and Greenland.[12]

## Other analyses

This project is concerned with whether housing circumstances are contributing to the risk of disease, independent of other characteristics, and will use additional methods to control for a range of other confounding effects.

The administrative data used in this report is based on RENTEL data collected and entered by HNZC staff. There are inevitably some errors in this process. Except for missing values and obvious data entry errors, the researchers cannot identify or assess the extent of such errors. To do this would require a separate validation study (or studies). The need for such a study will be assessed by conducting sensitivity analyses of final results.

## 4 Quality and completeness of data

### 4.1 Needs assessment interviews

The Needs Assessment interview collects information on various factors that are important for deciding the need for housing and the income related rent if re-housed. Several fields were added to the NA form to support operation of the cohort study, notably questions on the number of other people in the house, total number of bedrooms in the house and duration of living in this situation i.e. with this number of people in this current house.

### 4.1.1 Interviews by month

The total number of Needs Assessment interviews conducted in the 12-month period from July 2003 to June 2004 was 29970 and from July 2004 to June 2005 was 30344. There were, on average, around 2510 interviews conducted each month with a range from 1993 to 2938. Note that this includes change of circumstances where another full interview may not be necessary.

Table 4.1 presents the number of Needs Assessment interviews conducted each month by HNZC (where the status of the application has been confirmed). The percentage for that month out of the total for the year is shown in the third column.

It was expected that the information for housing applicants would be fairly complete as it was obtained from an interview. However, there were initially a large number of missing values for some variables. After discussion with HNZC front line staff and management it appeared that most of the missing values were in fact zeros (i.e. none or zero recorded on the Needs Assessment form) but were being recorded as missing values through a lack of understanding of the difference and through the computer system allowing missing values. Table 4.2 shows the response rates for the five variables that were added to the NA interview. The response rates have been analysed for seven time periods (shown in the first column). The groupings were chosen to represent points in time that should have some impact on the response rate. The first grouping is the first two months of data collection when the new Needs Assessment form was being introduced - consequently these months have the lowest response rate.

Table 4.1: Number of needs assessment interviews by month, February 2003 to June 2005

| Month | Number of Interviews | Percent (of total for the 12 months) |
| :---: | :---: | :---: |
| February (2003) | 2598 | Not included* |
| March | 2669 | Not included |
| April | 2467 | 8.3 |
| May | 2522 | 8.5 |
| June | 2235 | 7.5 |
| July | 2618 | 8.7 |
| August | 2410 | 8.0 |
| September | 2542 | 8.5 |
| October | 2562 | 8.5 |
| November | 2399 | 8.0 |
| December | 2257 | 7.5 |
| January (2004) | 2150 | 7.2 |
| February | 2524 | 8.4 |
| March | 2917 | 9.7 |
| April | 2536 | 8.5 |
| May | 2594 | 8.6 |
| June | 2461 | 8.2 |
| Total (for 12 months) | 29970 | 100.0 |
| July | 2468 | 8.1 |
| August | 2792 | 9.2 |
| September | 2924 | 9.6 |
| October | 2873 | 9.5 |
| November | 2938 | 9.7 |
| December | 2209 | 7.3 |
| January (2005) | 1993 | 6.6 |
| February | 2526 | 8.3 |
| March | 2544 | 8.4 |
| April | 2403 | 7.9 |
| May | 2424 | 8.0 |
| June | 2250 | 7.4 |
| Total (for 12 months) | 30344 | 100.0 |

*Note February and March 2003 are not included in the analysis as the study and new forms were being phased in over that period.

Table 4.2: Completeness of key crowding variables from the needs assessment interview, February 2003 to June 2005

| Months | Response Rates (\%) |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  | Other People | Total Bedrooms | Other Rooms | Weeks in <br> Accommodation |
| Feb-Mar 2003 | 31.9 | 39.5 | 21.8 | 33.2 |
| Apr-Jul 2003 | 37.9 | 44.6 | 24.2 | 37.1 |
| Aug-Dec 2003 | 40.5 | 49.5 | 25.7 | 43.4 |
| Jan-Mar 2004 | 47.7 | 57.1 | 31.7 | 52.8 |
| Apr-Jul 2004 | 50.4 | 62.4 | 34.3 | 57.9 |
| Aug-Dec 2004 | 100.0 | 99.9 | 99.7 | 99.8 |
| Jan-Jun 2005 | 100.0 | 100.0 | 100.0 | 100.0 |

HNZC took steps to improve the completeness of this data by establishing the housing variables as mandatory fields in a new release of RENTEL that became active in August 2004. In preparation for this change an email was sent in late December 2003 to all front line staff outlining how the four variables above should be handled and warning that they will, in the near future, become mandatory fields. The response rate from December to January shows a slight increase for these four variables (see Figure 4.1.) The response rate increased to $100 \%$ from August 2004 after HNZC set the four crowding variables as mandatory fields.

The other variables from the Needs Assessment have negligible numbers of missing values.

Figure 4.1: Response rates for the key crowding variables across time

### 4.1.2 Response to the ethnicity question in the NA interview

Use of the ethnicity field is more complex. This field was extensively modified in the revised Needs Assessment questionnaire released in February 2003, making ethnicity recording comparable to the method used by Statistics NZ (Census 2001). In particular, the revised form provided the ability to enter multiple ethnicities for each housing applicant.

Figure 4.2 shows that the response rate to this question remained high. A particular change over time is that more applicants are reporting multiple ethnicities. Note that the "other" ethnic group is counted only once even if multiple ethnicities were entered into the comment within this field.

Figure 4.2: Response to ethnicity question on NA interview by month, February 2003 to June 2005

### 4.2 IRR assessment

The following section looks at information for the HNZC tenants based on completed IRR forms entered by HNZC from February 2003 to June 2005. These data exclude tenants not claiming an IRR, i.e. those paying market rent. This number is estimated at approximately 1750 tenancies. ${ }^{2}$

[^1]
### 4.2.1 Interviews by month

The total number of IRR forms entered into RENTEL over the 12-month period from July 2003 to June 2004 was 75041 and from July 2004 to June 2005 was 75881 . The number of completed forms each month averaged about 6269 ranging from a minimum of 5059 to a maximum of 7598 . Table 4.3 shows the monthly number of IRRs completed.

Table 4.3: Number of IRR forms completed by month, February 2003 to June 2005

| Month | Number of IRRs | Percent (of total for the 12 months) |
| :---: | :---: | :---: |
| February (2003) | 7082 | Not included |
| March | 6242 | Not included |
| April | 5059 | 6.8 |
| May | 6618 | 8.9 |
| June | 5883 | 7.9 |
| July | 7160 | 9.5 |
| August | 6290 | 8.4 |
| September | 6785 | 9.0 |
| October | 5455 | 7.3 |
| November | 5265 | 7.0 |
| December | 6382 | 8.5 |
| January (2004) | 6036 | 8.0 |
| February | 5679 | 7.6 |
| March | 7598 | 10.1 |
| April | 6052 | 8.1 |
| May | 6205 | 8.3 |
| June | 6134 | 8.2 |
| Total (for 12 months) | 75041 | 100.0 |
| July | 6544 | 8.6 |
| August | 6246 | 8.2 |
| September | 6383 | 8.4 |
| October | 5177 | 6.8 |
| November | 6452 | 8.5 |
| December | 6445 | 8.5 |
| January (2005) | 5458 | 7.2 |
| February | 6541 | 8.6 |
| March | 6862 | 9.0 |
| April | 6185 | 8.2 |
| May | 7182 | 9.5 |
| June | 6406 | 8.4 |
| Total (for 12 months) | 75881 | 100.0 |

### 4.2.2 Completeness of the data

Table 4.4 shows results for two new fields added to the revised IRR form released in February 2003: ethnicity, and a voluntary smoking question. These results show that by June 2005, the ethnicity field was being completed by $95 \%$ and the voluntary smoking field by $63 \%$. These trends are described in more detail below.

Table 4.4: Completeness of key variables from the IRR form, February 2003 to June 2005

| Months | Response Rates (\%) |  |
| :--- | :---: | :---: |
|  | Ethnicity | Smoking <br> (Adult tenants only) |
| Feb-Mar 2003 | 70.0 | 24.4 |
| Apr-Jul 2003 | 79.7 | 46.4 |
| Aug-Dec 2003 | 84.6 | 50.6 |
| Jan-Mar 2004 | 87.7 | 55.4 |
| Apr-Jul 2004 | 89.8 | 57.4 |
| Aug-Dec 2004 | 92.6 | 60.1 |
| Jan-Mar 2005 | 94.0 | 62.0 |
| Apr-Jun 2005 | 95.1 | 62.5 |

### 4.2.3 Voluntary response to the smoking question

Figure 4.3 shows the monthly trend for increasing response rates to the smoking question. The number answering this question [the line with $\square$ ] increased initially but is now flattening off. The current response rate is now about $63 \%$.

Figure 4.3: Response to smoking question on IRR form by month, February 2003 to June 2005

Month

Table 4.5 shows that the voluntary smoking question was most likely to be completed by those aged 50 years or more. It was least likely to be completed by those aged $18-29$ years. Females had a slightly higher response rate than males and NZ Europeans were the ethnic group with the highest response rate. Those who did not state their ethnicity were also poor responders to the smoking question. The response rate appears particularly low ( $37.2 \%$ ) for people recorded as "Other People" i.e. non-tenants and non-partners, as expected.

Table 4.5: Characteristics of people completing the smoking questions on the IRR form, April 2003 to June 2005

| Characteristic | Total Number Adults IRRs ${ }^{1}$ | Smoking |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Yes | No | Not stated | Response rate \% |
| 18-29 years | 75429 | 9963 | 16487 | 48960 | 35.1 |
| 30-49 years | 124719 | 29199 | 47047 | 48426 | 61.1 |
| 50-69 years | 62837 | 11297 | 29671 | 21862 | 65.2 |
| 70+ years | 25337 | 1895 | 14986 | 8453 | 66.6 |
| Male | 114662 | 20176 | 40176 | 54270 | 52.6 |
| Female | 173658 | 32177 | 68015 | 73430 | 57.7 |
| NZ European ${ }^{2}$ | 79188 | 16882 | 32971 | 29312 | 63.0 |
| Maori ${ }^{3}$ | 85890 | 23710 | 23376 | 38767 | 54.8 |
| Pacific ${ }^{4}$ | 80445 | 9882 | 37169 | 33377 | 58.5 |
| Other | 29157 | 2961 | 13149 | 13045 | 55.3 |
| Not Stated | 26053 | 1844 | 5596 | 18610 | 28.6 |
| Tenants | 266206 | 51345 | 105277 | 109509 | 58.8 |
| Partners ${ }^{5}$ | 4613 | 576 | 1827 | 2210 | 52.1 |
| Other People | 82847 | 10718 | 20065 | 52035 | 37.2 |
| Total | 288322 | 52354 | 108191 | 127701 | 55.7 |

[^2]
### 4.2.4 Response to the ethnicity question

Figure 4.4 shows the response to the ethnicity question for the tenants. There has been a steady increase in the number of people reporting both sole and multiple ethnicities and a corresponding reduction in the number of missing values.

Figure 4.4: Response to ethnicity question on IRR form by month, February 2003 to June 2005

### 4.3 Quality of data matching

The data from May 2003 to June 2005 have been matched with hospital discharge records. As described, NZHIS uses four data fields (first given name, surname, sex, and date of birth) to identify the National Health Index (NHI) number for members of the cohort. This process uses electronic matching, followed by manual matching. The NHI is supplied in an encrypted version with each cohort record. The researchers use this number to identify hospitalisations in the national hospitalisations file.

This section reviews the completeness and quality of this data matching process and potential errors that this process could introduce into the study.

### 4.3.1 Completeness of data matching

The overall proportion matched for the 26-month period May 2003 to June 2005 was $91.7 \%$. Electronic matching was achieved for approximately $65 \%$ of records, based on an exact match with the 4 fields used. A further $35 \%$ of records where manually matched by trained NZHIS clerical staff.

Figure 4.5 shows the proportion matched by month over the 26 -month period. The total proportion of matched records changes little over this period.

Figure 4.5: Match rate by month, May 2003 to June 2005

### 4.3.2 Potential errors with data matching and the NHI

Two identification keys can be used to identify unique individuals in the cohort study population:

- The NHI number, which is assigned by NZHIS based on identifying information provided by HNZC. This is recorded as an encrypted NHI so that it is not possible for researchers to identify the person even if they have access to NHI codes.
- A housing identification (ID2) number generated by the research team for each person in the HNZC applicant and tenant data supplied via NZHIS. The ID2 number is generated by combining the tenant reference number (irr_tnnt_ref, a unique reference number that HNZC assigns to each household within the four main regions (comp_ref)) and the household reference number (hhld_ref, a unique reference number that HNZC assigns to each person within a household). Concatenating these three numbers gives ID2.

Potential errors with data matching can be assessed by comparing these two numbers. In a stable tenancy situation with perfect matching each NHI should correspond to a single ID2. However, conflict exists in the merged dataset.

The following tables compared NHI to ID2. Firstly by using the NHI as the reference field and seeing how ID2 numbers match to this. Then by using the ID2 as the reference field and seeing how the NHI numbers match to this.

Table 4.6: Comparison of cohort members based on their NHI to see how many have multiple housing reference (ID2) numbers, (May 2003 to June 2005)

| Pattern | Number | $\%$ |
| :--- | ---: | :---: |
| 1 ID2 to 1 NHI | 206560 | 79.58 |
| 2 ID2 to 1 NHI | 43700 | 16.84 |
| 3 ID2 to 1 NHI | 7664 | 2.95 |
| 4 ID2 to 1 NHI | 1342 | 0.52 |
| 5 ID2 to 1 NHI | 217 | 0.08 |
| 6 ID2 to 1 NHI | 51 | 0.02 |
| 7 ID2 to 1 NHI | 8 | 0.00 |
| 8 ID2 to 1 NHI | 4 | 0.00 |

Table 4.7: Comparison of cohort members based on their housing reference (ID2) number to see how many have multiple NHI numbers, (May 2003 to June 2005)

| Pattern | Number | $\%$ |
| :--- | ---: | ---: |
| 1 NHI to 1 ID2 | 317777 | 90.35 |
| 2 NHI to 1 ID2 | 4657 | 1.32 |
| 3 NHI to 1 ID2 | 45 | 0.01 |

This analysis shows that while individuals identified by NHI numbers sometime ( $20 \%$ of the time) have multiple ID2 numbers, the converse is not true. i.e. Individuals identified by ID2 numbers rarely ( $1.3 \%$ of the time) have multiple NHI numbers linked to them.

The population of individuals where the NHI number links to multiple ID2 numbers represent people who supplied information to HNZC more than once during the year (through NA, IRR, change in circumstances), and

- Changed tenancies and received a new tenant reference number in the process; or
- Exited from being a HNZC tenant and then re-entered during the same year receiving a new tenant reference number in the process.

The much smaller group of individuals represented by ID2 numbers with multiple (usually just two) NHI numbers represents:

- People who supplied information to HNZC more than once during the year (NA, IRR, change in circumstances); and
- Were subject to a data matching error (the same person was matched to NHI for two different people); or
- The same person had more than one NHI number.

### 4.3.3 Characteristics of matched and un-matched participants

Table 4.9 shows the characteristics of people who were and were not matched with NHI numbers, based on a year of data provided by NZHIS. As this analysis shows, matching was more complete for subjects with the following characteristics: 30-69 years of age, female, New Zealand European and tenants (some of these characteristics are related to one another, so further analysis would be required to determine the separate contribution of each).

### 4.4 Other data issues

### 4.4.1 Data entry errors

A number of fields have problems with obvious data entry errors i.e. contain values that are implausible. The recording of other people in the applicant household along with the total number of bedrooms and duration in accommodation has already been discussed in detail in the previous section. The income field at times records spurious values that are obvious data entry errors. There does not appear to be any system check to limit the size of the weekly income entered or to warn if unlikely values are being entered.

The Canadian National Occupancy formula relies on knowing the number of couples in the household. This information is recorded poorly for both the applicants and tenants. The IRR household structure field is not necessarily a true reflection of couple status as this field is used to determine whether they are viewed as a couple for income purposes. The partner code in the signatory relate field is only used if the individual is not a signatory. The combination of these
two fields does not appear to distinguish adequately households with couples from say two single adults or households with more than one couple.

Disposable income provides a measure of the socio-economic status of the household. Presently the tenant's disposable income can be measured using the income- related rent, however this same measure cannot be calculated for the applicants as the current rent or housing costs are not in the WSM\&HS datasets. The disposable income and change in disposable income may have an impact on both the crowding levels and health status of the occupants and will be of interest in the shift from applicant status to tenant.

### 4.4.2 Comparison of ethnicity data from multiple sources

As noted in the methods section (3.3.2), the analyses presented in this report use ethnicity data from 3 different sources. The following table presents these data according to key characteristics that affect their comparability: Proportions in different categories, notably "Other" and "Not stated" and the proportion using non-ethnicity categories such as "New Zealander". This presentation if based on inclusive coding, which means that individuals are represented in all of the categories in which they record themselves. It also notes the proportion using multiple ethnicities.

Table 4.8: Comparison of ethnicity recording characteristics across different data sources (HNZC, NZHIS, Census)

|  | Housing applicants (HNZC) |  | Housing tenants (HNZC) |  | Hospital discharges (NZHIS) |  | NZ population (Census) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Frequency | Percent | Frequency | Percent | Frequency | Percent | Frequency | Percent |
| New Zealand European | 6639 | 25.1 | 47055 | 23.8 | 1263562 | 70.0 | 2871423 | 76.8 |
| Maori | 8869 | 33.5 | 69823 | 35.3 | 300106 | 16.6 | 516278 | 13.8 |
| Pacific | 7074 | 26.7 | 69357 | 35.1 | 129708 | 7.2 | 231785 | 6.2 |
| Asian | 2352 | 8.9 | 6213 | 3.1 | 87971 | 4.9 | 237459 | 6.4 |
| Other | 2822 | 10.7 | 8772 | 4.4 | 58063 | 3.2 | 24984 | 0.7 |
| Not Stated | 567 | 2.1 | 14279 | 7.2 | 27173 | 1.5 | 140512 | 3.8 |
| Total | 28323 | 107.0 | 215517 | 108.9 | 1805012 | 103.9 | 3737025 | 107.6 |

Table 4.9: Characteristics of cohort participants who were matched with NHI numbers and those who were un-matched, May 2003 to June 2005

| Characteristic | $\begin{gathered} \text { Direct } \\ \text { match (\%) } \end{gathered}$ | Manual match (\%) | Total match (\%) | Un- matched (\%) |
| :---: | :---: | :---: | :---: | :---: |
| Age group |  |  |  |  |
| 0-17 years | 65.41 | 25.34 | 90.75 | 9.25 |

| 30-49 years | 67.59 | 25.90 | 93.50 | 6.50 |
| 50-69 years | 61.20 | 32.35 | 93.56 | 6.44 |
| 70+ years | 50.35 | 40.11 | 90.45 | 9.55 |
|  | 0.00 | 0.00 |  |  |
| Sex |  |  |  |  |
| Male | 65.32 | 25.63 | 90.94 | 9.06 |
| Female | 65.09 | 27.21 | 92.30 | 7.70 |
| Ethnicity ${ }^{1}$ |  |  |  |  |
| NZ European | 69.69 | 25.68 | 95.36 | 4.64 |
| Maori ${ }^{2}$ | 66.49 | 25.80 | 92.30 | 7.70 |
| Pacific ${ }^{3}$ | 63.39 | 26.43 | 89.83 | 10.17 |
| Asian | 59.52 | 28.12 | 87.64 | 12.36 |
| Other | 63.05 | 27.90 | 90.95 | 9.05 |
| Not Stated | 60.68 | 28.28 | 88.95 | 11.05 |
| Housing <br> applicants (NA) | 68.31 | 22.89 | 91.19 | 8.81 |
| Tenants (IRR) |  |  |  |  |
| - Tenants | 65.09 | 30.84 | 95.93 | 4.07 |
| - Partners ${ }^{4}$ | 63.98 | 23.49 | 87.47 | 12.53 |
| - Dependent children | 66.45 | 25.72 | 92.16 | 7.84 |
| - Other People | 58.31 | 25.98 | 84.29 | 15.71 |
| - Total | 64.68 | 27.82 | 92.50 | 7.50 |
| Total | 65.19 | 26.50 | 91.69 | 8.31 |

${ }^{1}$ The response rates by ethnicity groups were calculated inclusively. This means that a person who ticked both NZ European and Maori, for example, would get counted in both groups.
${ }^{2}$ This does not include those of Maori ethnicity who wrote their ethnicity in the "others" category.
${ }^{3}$ This does not include those of Pacific ethnicity who wrote their ethnicity in the "others" category.
${ }^{4}$ This is calculated using the partner code in the field for the relationship to the signatory. This is different to the couples code in the IRR form

## 5 Characteristics of the applicants

The cross section of applicant data as at the 30th of June 2005 contains a total of 9976 households with 26484 individuals. The following section presents the characteristics of this cross section of applicant data including an analysis of the crowding measures.

### 5.1 Household Demographics

The following sections present analyses of the household demographics of the applicants (all household members). Section 5.1.1 presents the age distribution, Section 5.1.2 the sex distribution and ethnicity is presented in Section 5.1.3.

### 5.1.1 Age Distribution of the housing applicants

The age distribution of the applicants (all household members) is presented in Figure 5.1. This histogram shows there are a large number of young people (aged less than 18 years) in the applicant households. There is a small peak in the number of mid- thirty year olds. The distribution has a long tail to the right with maximum age of 106 years. The mean and five number summary are presented in Table 5.1. The mean age is 25 years and the median age is 19 years reflecting the skew in the data. The relatively small number of infants $(<1$ year of age) is an artefact caused by the fact that babies born into applicant households after the date of the Needs Assessment interview would not be counted.

Figure 5.1: Age distribution of the applicant household members at June 2005

Table 5.1: Summary statistics for the age distribution of people in applicant households at June 2005

| Summary Statistics | Age |
| :--- | ---: |
| N | 26484 |
| Mean | 25.1 |
| Min | 0.1 |
| Lower Quartile | 7.7 |
| Median | 19.5 |
| Upper Quartile | 38.9 |
| Max | 105.6 |

### 5.1.2 Sex distribution of the housing applicants

Table 5.2 presents the sex distribution for the applicants. There are slightly more females ( $57.4 \%$ ) than males ( $42.6 \%$ ) possibly related to the high proportion of one parent households in the applicant population. This variable had no missing values.

Table 5.2: Sex distribution of people in housing applicant households at June 2005

| Sex | Frequency | Percent |
| :--- | ---: | ---: |
| Female | 15195 | 57.4 |
| Male | 11289 | 42.6 |
|  |  |  |
| Total | 26484 | 100.0 |

### 5.1.3 Ethnic Characteristics of the housing applicants

The ethnic composition, both exclusive (prioritised) and inclusive, is presented in Table 5.3 (see methods section for an explanation of these classification systems). The inclusive coding increases the number of NZ European and to a lesser degree the number of Pacific Island people, Asian and Other. The numbers of Maori and Not Stated remain the same. The largest ethnic group is Maori followed by Pacific People and NZ European.

Table 5.3: Ethnicity of people in housing applicant households at June 2005, based on exclusive and inclusive coding

| Ethnicity | Exclusive coding |  | Inclusive coding |  |
| :--- | ---: | ---: | ---: | ---: |
|  | Frequency | Percent | Frequency | Percent |
| New Zealand European | 5561 | 21.0 | 6639 | 25.1 |
| Maori | 8869 | 33.5 | 8869 | 33.5 |
| Pacific | 6664 | 25.2 | 7074 | 26.7 |
| Asian | 2283 | 8.6 | 2352 | 8.9 |
| Other | 2540 | 9.6 | 2822 | 10.7 |
| Not Stated | 567 | 2.1 | 567 | 2.1 |
|  |  |  |  |  |
| Total | 26484 | 100.00 | 28323 | 107.0 |

### 5.2 Household Structure and income

The following analyses describe the household structure and income of the applicant households. Jensen (1988) equivalised income weights are used to adjust for household size and composition (See methods section).

### 5.2.1 Structure of the applicant households

The composition for the applicant households is presented in Table 5.4. One adult with children households make up $42.7 \%$ of the applicant households. Very few applicants are single and aged less than 24 years with no children. Couples without children also make up a relatively small number of the applicants ( $11 \%$ ).

Table 5.4: Applicant household structure

| Household Structure | Frequency | Percent |
| :--- | :---: | ---: |
| One adult, 24 or under, No children | 284 | 2.8 |
| One adult, 25 or over | 2524 | 25.3 |
| One adult, 1 child | 1924 | 19.3 |
| One adult, 2 or more children | 2338 | 23.4 |
| Couple, No children | 1127 | 11.3 |
| Couple, 1 or more children | 1779 | 17.8 |
| Total | 9976 | 100.0 |

The percentage of households with varying numbers of children and adults are shown in Table 5.5. The first row shows that $69 \%$ of the applicant households have one adult and $27 \%$ have two adults. $62 \%$ of the households have one or more children.

Table 5.5: Applicant household numbers at June 2005

| NumberofAdults | Number of Children |  |  |  |  |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0 | 1 | 2 | 3 | 4 | 5 | 6+ |  |
| 1 | 26.3 | 19.7 | 12.8 | 5.9 | 2.8 | 1.3 | 0.5 | 68.6 |
| 2 | 10.2 | 5.6 | 4.6 | 2.9 | 1.7 | 0.8 | 0.5 | 26.5 |
| 3 | 1.3 | 1.0 | 0.6 | 0.4 | 0.3 | 0.1 | 0.1 | 3.8 |
| 4+ | 0.3 | 0.3 | 0.2 | 0.2 | 0.1 | 0.0 | 0.1 | 1.1 |
| Total | 38.1 | 26.2 | 18.1 | 9.4 | 4.8 | 2.2 | 1.1 | 100.0 |

### 5.2.2 Income of the applicant households

Table 5.6 presents summaries of the total weekly household income and the equivalised total weekly household income. The average total weekly income of the applicant households is $\$ 270$ and this reduces to $\$ 268$ when equivalised for household size. The income equivalisation does not affect the bottom fifty percent of the income distribution to any large degree. The income equivalisation has spread the distribution out whilst reducing the highest values as shown by the increase in the interquartile range ( $\$ 81$ before equivalisation increased to $\$ 104$ after equivalisation) and the reduction in the maximum weekly income from $\$ 1000$ per week to $\$ 784$ per week. This table also shows that $75 \%$ of the applicants have an equivalised income less than or equal to $\$ 315$ per week.

Histograms of the weekly income for the applicant households are shown in Figure 5.2. The total weekly income is presented in Figure 5.2 (a) and the equivalised income in Figure 5.2(b). These histograms show the effect of the income equivalisation, which spreads the distribution out more and reduces the upper tail.

Table 5.6: Summary statistics of the total weekly applicant household income

| Summary <br> Statistics | Income <br> $(\mathrm{n}=9976)$ | Equivalised <br> Income <br> $(\mathrm{n}=9976)$ |
| :--- | :---: | :---: |
| Mean | 270.01 | 268.33 |
| Min | 0.00 | 0.00 |
| Lower Quartile | 213.12 | 211.82 |
| Median | 245.30 | 258.37 |
| Upper Quartile | 290.72 | 315.66 |
| Max | 1000.00 | 784.62 |

Figure 5.2: Income of the applicant households, based on total household income per week at June 2005

The number of people in each household receiving a Government benefit is presented in Table 5.7. The first column shows the number of household members receiving a benefit, the second column the number of households followed by the percent. For the applicants the maximum number of family members receiving a benefit was observed to be 4 , with 2 households in this situation. Twenty-one percent of the applicant households had no family member receiving a benefit. The most common situation, $64 \%$ of households, is for one household member to be receiving a benefit.

Table 5.7: Number of households with members receiving a Government benefit

| Number <br> receiving a <br> Benefit | Number of <br> Households | Percentage of <br> Total <br> Households |
| :--- | :---: | :---: |
| 0 | 2128 | 21.3 |
| 1 | 6378 | 63.9 |
| 2 | 1419 | 14.2 |
| 3 | 49 | 0.5 |
| 4 | 2 | 0.0 |
| Total <br> Households | 9976 | 100.0 |

### 5.3 Crowding Level

This section investigates the crowding levels of the applicant households using three measures: household size, people per bedroom and the Canadian National Occupancy Standard (CNOS). These measures use two key variables, number of people in the household and the number of bedrooms in the house. The household sizes are presented in Section 5.3.1, the number of bedrooms in Section 5.3.2, and the crowding levels in Section 5.3.3. The reported length of time that people have been living in those circumstances is presented in Section 5.3.4.

### 5.3.1 Household Size

The total size of the households is determined by both the size of the applicant household, and the size of any non-applicant household they are staying with at the time. The average number of people living in the house and the five number summary are shown in Table 5.8. The mean household size is 4.0 people. Seventy-five percent of households consisted of five people or less. The maximum value of 53 appears to be a data entry error.

Table 5.8 also shows a breakdown between applicants who are sharing with non-applicants and applicants who are not sharing (i.e. the whole household is waiting to be housed). About a third of the applicant households are sharing with non-applicants. The average total household size for non-sharers is 2.8 compared with 6.1 for those who are sharing with non-applicants. The five number summary is also smaller for those who are not sharing.

Table 5.8: Summary statistics for the applicant household size

| Summary <br> Statistics | Applicants <br> Not Sharing | Applicants Sharing <br> with Other People | All Applicants |
| :--- | :---: | :---: | :---: |
| N | 6281 | 3695 | 9976 |
| Mean | 2.8 | 6.1 | 4.0 |
| Min | 1 | 2 | 1 |
| Lower Quartile | 1 | 4 | 2 |
| Median | 2 | 6 | 3 |
| Upper Quartile | 4 | 8 | 5 |
| Max | 10 | 53 | 53 |

Table 5.9: Applicant household size, including contribution from non-applicants living in the same house at June 2005

| Household Size | Applicants |  | Non-Applicants ${ }^{1}$ |  | Total |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Number of Households | Percent of Households | Number of Households | Percent of Households | Number of Households | Percent of Households |
| 0 or missing | -- | -- | 6281 | 62.9 | -- | -- |
| 1 | 2634 | 26.4 | 717 | 7.2 | 1617 | 16.2 |
| 2 | 2928 | 29.4 | 708 | 7.1 | 1957 | 19.6 |
| 3 | 1956 | 19.6 | 631 | 6.3 | 1672 | 16.8 |
| 4 | 1179 | 11.8 | 509 | 5.1 | 1366 | 13.7 |
| 5 | 670 | 6.7 | 415 | 4.2 | 983 | 9.8 |
| 6 | 349 | 3.5 | 248 | 2.5 | 759 | 7.6 |
| 7 | 155 | 1.6 | 157 | 1.6 | 519 | 5.2 |
| 8 | 71 | 0.7 | 123 | 1.2 | 367 | 3.7 |
| 9 | 23 | 0.2 | 64 | 0.6 | 216 | 2.2 |
| 10 | 10 | 0.1 | 47 | 0.5 | 182 | 1.8 |
| 11 |  |  | 26 | 0.3 | 102 | 1.0 |
| 12 |  |  | 18 | 0.2 | 75 | 0.8 |
| 13 |  |  | 5 | 0.1 | 60 | 0.6 |
| 14 |  |  | 4 | 0.0 | 32 | 0.3 |
| 15 |  |  | 7 | 0.1 | 20 | 0.2 |
| 16+ |  |  | 16 | 0.1 | 48 | 0.5 |
| Total | 9976 | 100.0 | 9976 | 100.0 | 9976 | 100.0 |

${ }^{1}$ Note this is using the field that records the total number of other people living in the house with the applicants and may not match the total number of other people described in the characteristics.

As can be seen from Table 5.9, 37\% of applicant households are living with non-applicants. This breakdown of household size shows that very few households are larger than 10 people. This Table shows the household size versus applicant or non-applicant status and the total distribution. The distribution of applicants has a much smaller maximum than the nonapplicants. It must be noted that the number of non-applicants in this table is calculated from the "total other people in the house" variable, which does differ from the total number of nonapplicants found using a sum of the characteristics. This is due to data entry errors.

The distribution of household sizes is shown in Figure 5.3 and shows a large right skew due to a number of extreme values that appear to be data entry errors rather than real data points (decided after discussion with HNZC).

Figure 5.3: Number of people in the applicant households at June 2005

Table 5.10: Applicant household size comparing applicants who share with nonapplicants to those who do not share at June 2005

| Household Size | Applicants Not Sharing |  | Applicants Sharing with Other People |  | All Applicants |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Number of Households | Percent of Households | Number of Households | Percent of Households | Number of Households | Percent of Households |
| 1 | 1617 | 25.7 | -- | -- | 1617 | 16.2 |

| $16+$ |  |  | 48 | 1.3 | 48 | 0.5 |
| Total | 6281 | 100.0 | 3695 | 100.0 | 9976 | 100.0 |

Table 5.10 presents the household sizes for applicants sharing with non-applicants, applicants not sharing and for all applicants. Again this table demonstrates the larger household sizes, as would be expected, for the applicants sharing with non-applicants.

### 5.3.2 Number of bedrooms in the applicant house

To calculate the number of bedrooms in the house for the crowding levels, the above variables have been incorporated in the following manner. If the "total bedrooms" is zero, then the "current bedrooms" is used instead, if the current number of bedrooms is also zero then the "other rooms used" is used instead. There are 263 records where all of these variables are either missing or zero.

The distribution of bedroom numbers across housing applicant households is shown in Figure 5.4. Most ( $87.4 \%$ ) houses have one to three bedrooms (or one to three rooms being used as bedrooms). Few ( $9.8 \%$ ) have four or more bedrooms.

Table 5.12 presents the summary statistics for the number of bedrooms in the current accommodation of the applicants. The mean number of bedrooms is 2.4. Seventy-five percent of the houses have three bedrooms or less. The maximum number of recorded bedrooms is 86 and is assumed to be a data entry error.

Table 5.11: Number of bedrooms in house used by housing applicants at June 2005

| Number of <br> Bedrooms <br> in House | Number of <br> Households | Percent of <br> Households |
| :--- | :---: | :---: |
| 0 | 263 | 2.6 |
| 1 | 1914 | 19.2 |
| 2 | 2748 | 27.5 |
| 3 | 4059 | 40.7 |
| 4 | 786 | 7.9 |
| 5 | 143 | 1.4 |
| $6+$ | 63 | 0.6 |
|  | 9976 | 100.0 |

Table 5.12: Summary statistics for the number of bedrooms in the applicant house

| Summary Statistics | Number of <br> Bedrooms |
| :--- | :---: |
| N | 9976 |
| Mean | 2.4 |
| Min | 0 |
| Lower Quartile | 2 |
| Median | 3 |
| Upper Quartile | 3 |
| Max | 86 |

Figure 5.4: Number of bedrooms in the applicant house (excluding four values > 10) at June 2005

### 5.3.3 Crowding levels of the applicant dwelling

The following tables present two measures of household crowding: household density based on people per bedroom, and bedroom deficit measured using the Canadian National Occupancy Standard (CNOS).

## Crowding levels measured by people per bedroom

One measure of crowding is to calculate the number of people per bedroom. A value of more than 2 is considered crowded as it is generally accepted that there should not be more than 2 people per bedroom. Some households will be crowded at levels between 1 and 2 people per bedroom depending on the mix of occupants. Two methods were used to calculate the people per bedroom for the applicants (see Section 3.3.3). The first method includes the number of non-applicants in the household and the total number of bedrooms. The second method uses the number of applicants only and the number of bedrooms to which they have access.

Table 5.13 shows the summary statistics for the number of people per bedroom calculated by the two different methods. The mean ( 1.7 people per bedroom) and median ( 1.5 people per bedroom) are higher for the first method than for the second method.

Table 5.14 shows the crowding levels calculated using the people per bedroom formula. The first method, which takes into account the non-applicants as well as applicants, estimates the proportion living in crowded conditions to be $36 \%$. In comparison, method 2 only looks at the applicants and the bedrooms to which they have access. The proportion overcrowded is smaller with $30 \%$ living in conditions with 2 or more people per bedroom.

Table 5.13: Summary statistics for the number of people per bedroom in the applicant house

| Summary <br> Statistics | Method 1 | Method 2 |
| :--- | :---: | :---: |
| \#Bedrooms=0 | 263 | 1349 |
| N | 9713 | 8627 |
| Mean | 1.7 | 1.6 |
| Min | 0.0 | 0.1 |
| Lower | 1.0 | 1.0 |
| Quartile | 1.5 | 1.3 |
| Median | 2.0 | 2.0 |
| Upper |  |  |
| Quartile | 30.0 | 10.0 |

Table 5.14: Crowding levels calculated using the people per bedroom formula

| People <br> per <br> bedroom | Percent of <br> Households <br> Method 1 | Percent of <br> Households <br> Method 2 |
| :--- | ---: | ---: |
| $0-0.99$ | 14.3 | 23.6 |
| $1-1.99$ | 49.7 | 46.0 |
| $2-2.99$ | 23.3 | 19.1 |
| $3-3.99$ | 8.2 | 6.8 |
| $4-4.99$ | 2.8 | 2.5 |
| $5-5.99$ | 0.9 | 1.3 |
| $6+$ | 0.8 | 0.7 |
|  |  | 100.0 |

Figure 5.5 shows the distributions of crowding in the applicant households using the two different measures discussed above. Due to the problems with recording of the other people in the house there are some extreme values of crowding levels with well over 30 people per bedroom recorded in some instances. These implausible values have been excluded from the histograms.

Housing applicant households can be divided into those who are sharing with others (62.1\%) and those who are not (37.9\%).
Table 5.15 presents a comparison of the crowding levels, using Method 1, between applicants sharing with non-applicants and those not sharing. The average people per bedroom is higher for those who share ( 2.3 people per bedroom) than for those who do not share with nonapplicants ( 1.4 people per bedroom). This is also shown in the 5 -number summary.

Figure 5.5: Crowding levels in the applicant households measured using people per bedroom at June 2005

Table 5.15: Summary statistics for the number of people per bedroom (Method 1) comparing applicants who share with other people to those who do not at June 2005

| Summary Statistics | Applicants Not <br> Sharing | Applicants Sharing <br> with Other People | All Applicants |

## Crowding levels measured by the Canadian National Occupancy Standard

Summary statistics for the CNOS are presented in Table 5.16. The Table shows a break down into applicants who share with non-applicants and those who do not. The applicants sharing have a higher mean room deficit and the same median as the applicants who do share with nonapplicants.

Table 5.17 shows the CNOS distributions for all applicants, applicants sharing with nonapplicants and applicants not sharing. This shows that $46.1 \%$ of housing applicants overall are living in crowded households based on CNOS of a one or more bedroom deficit. Crowding levels are much higher for applicant households sharing with others (79.8\%) compared with those who are not ( $26.1 \%$ ).

Table 5.16: Mean room deficit for housing applicants, based on CNOS, summary statistics at June 2005

| Summary Statistics | Applicants Not <br> Sharing | Applicants Sharing <br> with Other People | All Applicants |

| Total | 6281 | 100.0 | 3695 | 100.0 | 9976 | 100.0 |

### 5.3.4 Self reported duration in current situation

HNZC added a question to the NA interview about the length of time that the applicants had spent in their current housing situation. "How long, in weeks, have you been living in this situation, i.e. with this number of people in your current house." This question was being answered by $100 \%$ of the sample by June 2005 (compared with $51 \%$ in July 2004).

Table 5.18 shows the distribution of time the applicants report living in their current situation. Two categories show large groupings, that is the group that have spent 1 to 4 weeks in their current situation and the other group are those who have spent more than 52 weeks in their current situation. Duration of time in current situation can be used to define the time period for calculating hospitalisation rates in the applicant population.

Table 5.18: Length of time applicants have been living in current situation i.e. with this number of people and in current house at the time of the NA interview

| Weeks in current <br> accommodation | Frequency | Percent |
| :--- | :---: | :---: |
| Missing | 764 | 7.7 |
| 0 | 1589 | 15.9 |
| $1-4$ | 1583 | 15.9 |
| $5-12$ | 1055 | 10.6 |
| $13-24$ | 831 | 8.3 |
| $25-52$ | 1545 | 15.5 |
| 53+ | 2609 | 26.2 |
|  |  |  |
| Total | 9976 | 100.0 |

Table 5.19: Summary statistics for the duration in accommodation

| Summary Statistics | Weeks in <br> Accommodation |
| :--- | :---: |
| Missing Values | 764 |
| N | 9212 |
| Mean | 73.0 |
| Min | 0 |
| Lower Quartile | 2 |
| Median | 20 |
| Upper Quartile | 78 |
| Max | 999 |

Figure 5.6: Applicants duration in their current accommodation at the time of the NA interview at June 2005

Of those who answered this question, the average length in their current situation was 73 weeks but the median was 20 weeks indicating the degree to which the data is right skewed (see Table 5.19). The lower quartile is 2 weeks so twenty five percent of the applicants, who answered the question, have spent 2 weeks or less in their current situation. The upper quartile is 78 weeks. Twenty five percent of the applicants, who answered the question, have spent more than 78 weeks in their current situation. The maximum value of 999 weeks is the database limit for this field (corresponding to 19.2 years).

Figure 5.6 shows the distribution of time spent in the current accommodation. Figure 5.6(a) shows the full distribution. The distribution is very skewed and gives no sense of what is happening within the low range so the distribution is replotted in Figure 5.6(b) for values less than 53 weeks. There is a large peak in the duration times of about one to six weeks then the distribution declines until there is a large peak at a duration of 52 weeks indicating that people may tend to round their duration in accommodation to about one year when their duration in accommodation is just above or below one year.

### 5.3.5 Duration as housing applicant

The length of time the current applicants have been on the waiting list was calculated using the difference between the cross section date and the application-registered date. Table 5.20 shows that the average length of time on the waiting list for the current applicants is 50 weeks. The median is 32 weeks. Figure 5.7 presents the distribution of time spent on the waiting list for the current applicants. Most of the applicants have only been on the waiting list a short period of time but a few applicants have a duration of more than two years creating a long tail to the right of the distribution.

Note that this is not the average time it takes an applicant to get housed. The figure presented here is just the average length of time the current applicants have been on the waiting list. We would expect that the cross section will have few high need applicants that are housed quickly so to calculate the average time to housing these high turnover applicants would need to be taken into account along with the lower need applicants.

Table 5.20: Summary statistics for the length of time the current applicants have been on the waiting list

| Summary Statistics |  |
| :--- | :---: |
|  | Time on Waiting List |
| N | 9976 |
| Mean | 49.5 |
| Min | 0.0 |
| Lower Quartile | 13.0 |
| Median | 32.5 |
| Upper Quartile | 70.2 |
| Max | 437.4 |

Figure 5.7: Duration the cross section of applicants have been on the waiting list at June 2005

### 5.4 Characteristics of high and moderate priority applicants

Confirmed housing applicants are prioritised for housing based on information obtained during the Needs Assessment interview. The HNZC Social Allocation System aims to allocate housing according to need. It is based on accessing the level of risk the household faces across 5 categories (affordability, adequacy, suitability, accessibility, sustainability). Household are assigned a waiting list priority on an A to D scale. Table 5.21 shows the distribution of applicant households using this approach. Only a very small percentage of the applicants have been classed as the highest priority ( $2 \%$ classed as an A). The majority are classed as either a B or C. This finding is to be expected as a cross-section shows only 'prevalent' households that were priority 'A' at 30th June 2005, rather than all of those households who moved through this category (the longitudinal analysis in section 8 provides more information on the numbers of households who moved through these categories over the 18 month observation period).

Table 5.21: Prioritisation for HNZC housing

| Priority | Number of <br> Households | Percent of <br> Households |
| :--- | :---: | :---: |
| A | 198 | 2.0 |
| B | 3911 | 39.2 |
| C | 2843 | 38.5 |
| D | 9924 | 20.3 |
| Total | 976 | 100.0 |

HNZC considers those in categories A and B to be a high priority and those in categories C and D to have a moderate priority for housing. The characteristics of the high and moderate priority applicants are shown in Table 5.22 in comparison to the applicants as a whole. Forty one percent of the cross section of applicants were considered a high priority, that is 4112 households with 11672 people. The high priority applicants have spent a shorter time in their current accommodation at the time of the needs assessment and on average they have spent less time on the waiting list at the time of the cross section. A higher proportion of high priority applicants (44\%) are sharing with non-applicants compared with the moderate priority applicants ( $32 \%$ sharing).

The high priority applicant household members are, on average, younger than the moderate priority applicants. The inclusive ethnicity shows that Maori are over represented in the high priority group. There is a greater proportion of one-parent households in the high priority group. The high priority group also have lower incomes on average.

The final section of the table shows the crowding characteristics of the high and moderate priority applicants. The crowding measures show that the high priority group have, on average, more people in the household, more people per bedroom and a larger proportion short 1 or more bedrooms than the moderate priority group.

Table 5.22: Characteristics of high and moderate priority applicants at June 2005

| Characteristic | High Priority Applicants (A+B) | Moderate Priority Applicants (C+D) | Total housing applicants |
| :---: | :---: | :---: | :---: |
| Population |  |  |  |
| Number of households | 4112 | 5868 | 9976 |

| Short of 2 or more bedrooms (\%) | 35.8 | 17.8 | 25.7 |

## 6 Characteristics of the tenants

The characteristics of the HNZC tenants are presented in this section. This report uses the term "tenant" to cover all of those who are living in a HNZC property (tenants, partners, dependent children and other people). This analysis was done on the cross section of HNZC tenants as at June 2005. Section 6.1 describes the demographics of the tenants. Household structure and income are presented in Section 6.2. The smoking status of the tenants and active and passive smoking characteristics are examined in Section 6.3 and the crowding levels are analysed in Section 6.4.

### 6.1 Household demographics

The following section investigates the demographics of the HNZC tenants. Age, sex and ethnicity are presented.

### 6.1.1 Age distribution of the tenants

Figure 6.1 shows the distribution of ages of all the household members in the tenancy. There are two peaks to the right skewed distribution. The first and largest peak is for children aged between four and sixteen years. The second much smaller peak is for adults aged in their late thirties and early forties.

Figure 6.1: Age distribution of tenant household members at June 2005

Table 6.1 has the summary statistics for the age distribution of tenants. The average age is 28 and the median age 20 years, demonstrating the right skew of the data. The upper quartile is 43 years so seventy-five percent of the tenants are aged less than 43 years.

Table 6.1: Summary statistics for the age distribution of tenants

| Summary Statistics | Age |
| :--- | ---: |
| Missing Values | 3 |
| N | 197791 |
| Mean | 27.9 |
| Min | 0.1 |
| Lower Quartile | 10.4 |
| Median | 20.0 |
| Upper Quartile | 42.9 |
| Max | 105.6 |

### 6.1.2 Sex distribution of the tenants

Table 6.2 shows the sex distribution of tenants. Like the applicants there are more females ( $54.8 \%$ ) than males ( $45.2 \%$ ). There is one missing value.

Table 6.2: Sex distribution of people in tenant households at June 2005

| Sex | Frequency | Percent |
| :--- | :---: | :---: |
| Female | 108336 | 54.8 |
| Male | 89458 | 45.2 |
| Total | 197794 | 100.0 |

### 6.1.3 Ethnic characteristics of the tenants

The ethnic distribution of tenants, both coded exclusively and inclusively, is shown in Table 6.3. There are similar proportions of Maori and Pacific tenants (both about 35\%) and these two groups make up the majority of the tenants. The next largest group is New Zealand Europeans followed by those not stating any ethnicity. The difference between exclusive and inclusive coding mainly shows as an increase in the numbers of NZ Europeans and Pacific people in the inclusive coding. We can see that Asians make up a very small number of tenants, though with the moderate number of Not Stated this could have an impact on these numbers.

Table 6.3: Ethnicity of people in tenant households, based on exclusive and inclusive coding at June 2005

| Ethnicity | Exclusive coding |  | Inclusive coding |  |
| :--- | ---: | ---: | ---: | ---: |
|  | Frequency | Percent | Frequency | Percent |
| New Zealand European | 36507 | 18.5 | 47055 | 23.8 |
| Maori | 69823 | 35.3 | 69823 | 35.3 |
| Pacific | 64479 | 32.6 | 69357 | 35.1 |
| Asian | 5469 | 2.8 | 6213 | 3.1 |
| Other | 7237 | 3.7 | 8772 | 4.4 |
| Not Stated | 14279 | 7.2 | 14279 | 7.2 |
|  |  |  |  |  |
| Total | 197794 | 100.0 | 215517 | 108.9 |

### 6.2 Household structure and income

This section investigates the household structure and income of the HNZC tenants using information used to calculate the income related rent.

### 6.2.1 Structure of the tenant households

The household structure of the tenants using the classifications for the income related rent is shown in Table 6.4: Just over half the tenants have children in the household. One-parent households make up $35.5 \%$ of the tenant population using the IRR classification.

Table 6.4: Tenant household structure

| Household Structure | Frequency | Percent |
| :--- | ---: | ---: |
| Couple, 1 or more Children | 10968 | 17.9 |
| Couple, No Children | 5627 | 9.2 |
| One parent, 24 or under | 330 | 0.5 |
| One parent, 25 or over | 22434 | 36.7 |
| One parent, 1 Child | 7736 | 12.6 |
| One parent, 2 or more Children | 14023 | 22.9 |
|  |  |  |
| Total | 61118 | 100.0 |

Table 6.5 presents the percentage of households with varying numbers of adults and children. Of the tenant population a quarter $(24.8 \%)$ have one adult and no children. Fifty-two percent of the households contain only one adult with or without children and $40.6 \%$ of all the households have no children. Very few households (5.8\%) have four or more adults and very few ( $2.8 \%$ ) have six or more children.

Table 6.5: Tenant household numbers at June 2005

| Number <br> of <br> Adults | Number of Children |  |  |  |  |  |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  | 0 | 1 | 2 | 3 | 4 | 5 | $6+$ | Total |
| 1 | 24.8 | 8.6 | 8.3 | 5.8 | 2.9 | 1.2 | 0.8 | 52.4 |
| 2 | 11.4 | 5.3 | 5.3 | 4.4 | 2.8 | 1.5 | 1.3 | 32.0 |
| 3 | 2.9 | 2.1 | 1.8 | 1.3 | 0.9 | 0.4 | 0.4 | 9.8 |
| $4+$ | 1.4 | 1.2 | 1.2 | 0.8 | 0.6 | 0.3 | 0.3 | 5.8 |
| Total | 40.6 | 17.2 | 16.5 | 12.3 | 7.1 | 3.4 | 2.8 | 100.0 |

### 6.2.2 Income of the tenant households

The following section presents both total household income (total income relevant to the calculation of the IRR) and equivalised household income per week (equivalised using the Revised Jensen Scale) for tenants. Table 6.6 presents summary statistics for the household income both total per week and equivalised for household size. The average income is $\$ 305.55$ per week and this reduces to $\$ 279.70$ after equivalisation. Seventy-five percent of the tenants have an income of $\$ 351.22$ or less per week. The upper quartile of the equivalised income is $\$ 354.74$ per week.

Table 6.6: Summary statistics of the total weekly tenant household income

| Summary <br> Statistics | Income | Equivalised <br> Income |
| :--- | ---: | ---: |
| Missing Values | 61118 | 61118 |
| N | 305.55 | 279.70 |
| Mean | 0.00 | 0.00 |
| Min | 232.70 | 190.15 |
| Lower Quartile | 256.52 | 255.60 |
| Median | 351.22 | 353.74 |
| Upper Quartile | 2213.35 | 3076.92 |
| Max |  |  |

Figure 6.2 presents histograms of the total household weekly income per week and the equivalised income per week. Both distributions have a long right tail. The income equivalisation increases this long tail.

Table 6.7 shows the number of household members receiving a benefit in each tenancy. Only $8.9 \%$ of the tenant households have no members receiving a benefit. The majority of households ( $71.8 \%$ ) have one member receiving a benefit. Very few households have more than two members receiving a benefit.

Figure 6.2: Income of the tenant households per week (excluding 6 values greater than \$1500) at June 2005

Table 6.7: Number of household members receiving a benefit

| Number receiving <br> Benefit | Humber of <br> Households | Percent of <br> Households |
| :--- | :---: | :---: |
| 0 | 5412 | 8.9 |
| 1 | 43858 | 71.8 |
| 2 | 11564 | 18.9 |
| 3 | 244 | 0.4 |
| 4 | 35 | 0.1 |
| 5 | 4 | 0.0 |
| 6 | 1 | 0.0 |
|  |  | 100.0 |

### 6.3 Tobacco smoking

The following section reports the information gained from the smoking question that was added to the IRR form. The response rate to the question has been increasing with time.

### 6.3.1 Active smoking

Table 6.8 shows the reported prevalence of smoking ( 1 or more cigarettes per day), for the cross section of tenants at 30th June 2005. Currently around $63 \%$ of tenants (aged 18 or over) answer the 'smoking question'. The overall reported rates of smoking among those who answered this question was $31.7 \%$.

The breakdown of smoking prevalence by age group showed that those aged 18-29 years and 30-49 years had the highest prevalence (around 38\%) and those aged 70 or more had a very low prevalence of smoking of $10.9 \%$. Males and females have similar smoking prevalences of around $31 \%$. Of the ethnic groups Maori showed a relatively high prevalence of $49.7 \%$, much higher than the next group NZ European with a $31.5 \%$ prevalence. Tenants and "other people" had smoking prevalences of around $30 \%$ and people listed as partners were lower at $24 \%$. These numbers must be viewed with caution as $37 \%$ did not answer the smoking question and these people may have a different smoking profile to that presented in the table.

Table 6.8: Prevalence of reported smoking in adult tenants at June 2005

| Characteristic | Total <br> Number of <br> Adults | Smoking |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | 27074 | 3673 | Yes | No | Not stated | | Percentage |
| :---: |
| Smoking |

${ }^{1}$ Prevalence among those reporting smoking behaviour i.e. excluding not stated

### 6.3.2 Smoking households

Table 6.9 summarises the smoking status of households. From the smoking information for individuals, household smoking status was calculated. Note that only those aged 18 or over were asked about smoking behaviour therefore the household results do not allow for children who may actually be smoking.

About thirty percent of the households had complete information and the adults were all nonsmokers. Another $21.4 \%$ of households had complete information and at least one smoker. Six percent of households had at least one smoker and some unknowns. The remaining households were either all unknown or a mix of non-smokers and unknowns. In total there are 38155 ( $62 \%$ ) households that can be classified as either smoking or non-smoking households.

Table 6.9: Prevalence of reported household smoking status of tenants at June 2005

| Smoking status | Number of <br> Households | Percent of <br> Households |
| :--- | :---: | :---: |
| Non smoking household <br> Smoking household, total <br> - One or more reported <br> smoking adults, no <br> unknowns | 21170 | 34.6 |
| - One or more reported |  |  |
| smoking adults, and <br> one or more unknown | 3885 | 21.4 |
| One or more non-smokers <br> and the rest unknown <br> All Unknown household / <br> not stated | 6025 | 6.3 |
| Total | 61118 | 9.9 |

The structure of households according to their household smoking status is presented in Table 6.10. With the large degree of missing information on smoking status the results presented are not necessarily representative of the true distribution of smoking in the tenant population. For those with information available, the highest household smoking prevalences were found for one-parent households followed by couples with children. The lowest household smoking prevalence was in households with one adult aged 25 or more with no children.

Table 6.10: Prevalence of reported household smoking status of tenants, by household characteristics at June 2005

| Household type | Smoking household | Non smoking household | Unknown status | Percentage with at least one smoker in household ${ }^{1}$ |
| :---: | :---: | :---: | :---: | :---: |
| Couple, 1 or more children | 3051 | 3174 | 4743 | 49.0 |
| Couple, no children | 1383 | 2225 | 2019 | 38.3 |
| One parent, 24 or under | 72 | 77 | 181 | 48.3 |
| One parent, 25 or over | 5481 | 9628 | 7325 | 36.3 |
| One parent, 1 child | 2454 | 2179 | 3103 | 52.9 |
| One parent, 2 or more children | 4539 | 3892 | 5592 | 53.8 |
| Total | 16985 | 21170 | 22963 | 44.5 |

### 6.4 Crowding level

The following section investigates the crowding levels of the tenant households. The crowding measures are the same as those used for the applicants, namely total household size, people per bedroom and the Canadian National Occupancy Standard.

### 6.4.1 Household size

The distribution of household sizes is shown in Table 6.11. A quarter of the tenancies have one person. Very few households have more than five people in them, though there are some households with large numbers (sixteen or more). The average household size is 3.2 and the median is 3 (see Table 6.12). Seventy five percent of the tenancies have less than five people. The maximum number of people in one tenancy is 21 . Figure 6.3 shows the distribution of household sizes. There is a steady decrease in frequency as household size increases.

Table 6.11: Tenant household size at June 2005

| Household Size | Frequency | Percent |
| :---: | :---: | :---: |
| 1 | 15169 | 24.8 |
| 2 | 12237 | 20.0 |
| 3 | 10058 | 16.5 |
| 4 | 8635 | 14.1 |

### 6.4.2 Number of bedrooms in the tenant property

The number of bedrooms in the house, recorded in the property details, is presented in Table 6.13. This breakdown also includes the number of single and double bedrooms. Note that there are some properties that are considered to have no bedrooms and these are the pensioner/unit properties with no separate bedroom ('bed-sits'). The majority of properties have two or three bedrooms ( $82 \%$ ). Some properties have four bedrooms but this is only seven percent of the properties being used at 30th June 2005. Very few properties have more bedrooms than this. The average number of bedrooms is 2.5 and the median is 3 (see Table 6.14). The maximum number of bedrooms is 7. The distribution is shown in Figure 6.4.

### 6.4.3 Crowding levels of the tenant households

The following tables present two measures of household crowding: household density based on people per bedroom and bedroom deficit measured against the Canadian National Occupancy Standard (CNOS).

The average number of people per bedroom is 1.2 and the median is 1.0 (see Table 6.15). Table 6.16 presents the distribution of crowding levels as measured by people per bedroom for the housing tenants. The majority ( $59 \%$ ) have 1-1.99 people per bedroom. Very few households have four or more people per bedroom. The distribution of people per bedroom is shown in Figure 6.5. The distribution peaks at a crowding level of about 1.25 people per bedroom.

The distribution of households according to Canadian National Occupancy Standard crowding levels is shown in Table 6.18:. The majority (76\%) are not living in crowded conditions. The remaining $24 \%$ of households are classified as crowded as they have a one-room deficit or more.

### 6.4.4 Duration in current accommodation

The duration in the current accommodation is calculated as the difference between 30th June 2005 and the lease start date (measured using the anniversary date for technical reasons). The average tenancy length is 387 weeks ( 7 years) and the median is 246 weeks ( 4 years) (see Table 6.19:). The maximum length of accommodation recorded was 3395 weeks ( 65 years). The length of time spent in the tenancy is presented in Table 6.20:. The vast majority of tenants ( $84.5 \%$ ) have spent a year or more in their current house. Figure 6.6 shows the distribution of the time spent in the current accommodation. There is a large peak at the beginning of the distribution and then a long tail to the right.

Table 6.19: Summary statistics for the duration in accommodation

## 7 Comparison of the housing applicants and tenants

### 7.1 Household demographics, structure and income

Table 7.1 summarises the characteristics of the applicants and tenants and compares these two groups to the NZ population using 2001 census data. The applicants and tenants are, on average, younger than the NZ population. They are commonly one-parent families or one adult households. Maori and Pacific people are over represented in the applicant and tenant populations compared with the NZ population. The applicants and tenants have a relatively low household income with a high proportion receiving their income from a Government benefit.

Recall that the ethnicity for the applicants is recorded in an interview but is self reported for the tenants resulting in a much higher rate of missing values (NS - Not Stated) for the tenants. This high not stated rate for the tenants makes comparisons more difficult as the not stated could have a significant impact on the shape of the distribution.

### 7.2 Household size and crowding levels

Table 7.2 summarised measures of household size, house size and crowding of applicant and tenant populations and compares these with the New Zealand census population at the time of the 2001 census. On average the applicants have more people in the household and fewer bedrooms than the tenants and the tenants likewise have more people and fewer bedrooms than the total NZ population. The median number of people in the house is three for both applicants and tenants which is one more than the NZ population median. The median number of bedrooms for the applicants is two, which is one less then the median number of bedrooms for the tenants and NZ population.

The average people per bedroom is highest for applicants at 1.7 and lowest for the NZ population at 0.9. The table shows that the proportion in crowded households (both 1 or more bedrooms short and 2 or more bedrooms short) is higher for applicants than tenants and both are higher than for the total NZ population.

| Average people per bedroom <br> Short of 1 or more bedrooms \% <br> Short of 2 or more bedrooms \% | 1.7 | 1.2 | 0.9 |

Figures 7.1 to 7.4 present household size and crowding characteristics graphically for housing applicant and tenant households compared with the New Zealand population. These graphs also further split applicants into those who are sharing with other non-applicants and those who are not.

Figure 7.1 shows that applicants have the highest average household size, particularly those who are sharing with others. The applicants who are not sharing have a smaller average household size than the tenants but still larger than the average for the NZ population.

Figure 7.2 shows the average number of bedrooms for the applicants, tenants and New Zealand population. The applicants who are not sharing with others have the smallest number of bedrooms.

Figure 7.3 shows the average people per bedroom, which effectively combines the information presented in Figure 7.1 and

Figure 7.2. The graph shows that the applicants have the highest crowding by this measure and the tenants have higher crowding on average than the NZ population. The applicants who are sharing with other non-applicants have the highest crowding levels. Whilst the applicants who share have more bedrooms on average this is outweighed by their larger household size. The applicants not sharing had on average smaller households than the tenants but also had fewer bedrooms on average causing the overall average crowding by this measure to be higher than the tenants.

Figure 7.4 presents the percentage of households with a bedroom deficit of one or more. The graph shows a similar pattern but more pronounced trend to that shown by average people per bedroom. The applicants who are sharing with non-applicants have the highest crowding and

[^3]the tenants have the lowest crowding for the HNZC groups. All these groups have higher crowding than the NZ population.

Figure 7.4: Comparison of the percentage of households with bedrooms deficit of one or more at June 2005

## 8 Longitudinal analysis of applicant and tenant populations

### 8.1 Flows of households through HNZC processes

Figure 8.1 shows the cohort populations and potential flows between this and the New Zealand population. According to the 2001 NZ census there were 1344267 households in New Zealand on census night, implying a total of about 1280000 households if HNZC applicant and tenant households are excluded.

During February 2003 - June 2005, 37481 households were placed on the list of confirmed applicants. In that same 29 -month period, 13224 households recorded as applicants were housed. The actual number of applicants housed will be larger than this because the study does not record households who applied before the start date in February 2003. The newly housed applicants that we did not see as applicants first will reduce over time. Over this period there were at least 10720 exits from the tenants and at least 14281 exits from the applicant waiting list. The cross-section of applicants on the 30th June 2005 contained 9979 households (data from February and March 2003 were excluded for reasons explained previously) and the cross section of tenants included 61118 households (data from before June 2003 was excluded for reasons explained previously). A further group of households excluded from this analysis are those tenants not claiming an IRR, which is estimated at about 1750 ( $2.9 \%$ of total tenant household) in October 2004.

### 8.2 Repeated measurements of households

As described in Section 3.1, information is obtained from households about their circumstances at several key points:

- Applicant Needs Assessment interview
- Applicant Change of Circumstance
- Tenant Annual Income Related Rent application
- Tenant Change of Circumstance

Table 8.1describes the number of observations obtained for each household in the study population during the first 29 months operation, ignoring the exit data. Multiple tenant or applicant observations are not shown. Of the observed households, the majority are tenants during the study period (61.3\%) followed by applicants ( $24.5 \%$ ). The next largest group is those seen going from applicant to tenant (13.3\%). The study has been running long enough that a very small number of households have been through the process of applicant to tenant twice (68 households).

Figure 8.1: Graphic representation of cohort household populations and flows between them and the New Zealand population for 29 months (February 2003 - June 2005) Note that households who move through the HNZC applicant-tenant flow-chart more than once are counted once only

Table 8.1: Summary of applicant and tenant movement at June 2005

| Income | 424 | 5.4 | 5315 | 68.1 | 56.5 | 2067 | 26.5 | -77.3s |

*Variables covered in this analysis are: household size (number of people in household), number of bedrooms, crowding level (based on people/bedroom) and household income.

Households where there were repeat observations (Table 8.1) provide us with an opportunity to investigate changes in crowding and other variables, such as income, over time.
Table 8.2 shows the subset of households from Table 8.1 where there were multiple observations. The analysis focuses on the variables of household size (number of people), number of bedrooms, crowding level (based on people/bedroom) and household income. To simplify the analysis the first and last observation for each phase (applicant or tenant phases) were used to assess the change (final observation minus initial observation).
Table 8.2 shows three main change categories across the columns. The first category is households where no change in the particular variable was observed between first and last observation. The second category is where an increase in the variable was observed across time and the last category is where a decrease occurred. For the last two categories the average change (increase or decrease) has been calculated.

The first group of households tabulated are those who remained as applicants during the study period and had more than one observation. For this group the majority had no change in the four variables of interest. Small groups showed increases or decreases on these variables.

The second group are households who were tenants for the length of the study period. The majority showed no change on the three crowding measures, but most households had an increase in income.

The third group are applicants who have been housed and they are the most important for looking at changes in crowding levels ("APPL-TNNT with Changes in APPL-TNNT phase" in the table). Over a third ( $40.7 \%$ ) have a decrease in household size and this matches with a third of the cross section sharing with non-applicants. A similar proportion (37.8\%) has an average increase in the number of bedrooms upon housing of around 1.4 bedrooms. The combination of these two changes led to $61.6 \%$ of the applicants who were housed having a reduction in crowding, as measured by people per bedroom. The average reduction was 1.45 people per bedroom (from 2.64 people per bedroom as applicants to 1.19 people per bedroom at tenants). This group is important for the investigation of one of the main hypotheses of the study, which is that a change in crowding level gives a change in disease risk.

Table 8.3 also has two further groups for comparison. The applicants who were housed were also investigated for changes during either their phase as applicants or their phase as tenants. Again most of the households did not change their crowding levels in either of these stages.

### 8.3 Characteristics of high and moderate priority applicants

This report contains a brief analysis of the differences between priority groups A, B, C, and D as they move through the HNZC applicant-tenant process. Table 8.3 shows the possible trajectories. The main categories consist of being an applicant for the duration of the observation period, being an applicant then getting housed, or being an applicant then exiting the waiting list. The majority of applicants ( $89 \%$ ) fall into one of these three categories. The rest have more complex flows, with some moving through these populations more than once and others moving on and off the waiting list more than once.

For the simplest flows ( $89 \%$ of applicants) Table 8.4 shows the priority assigned to the applicants. The first column are the applicants who remained as applicants throughout the
observation period (includes some who had just been placed on the waiting list as well as those placed on it during the previous 28 months). The second column shows the applicants who exited the waiting list and the third shows the applicants who were housed. The final column shows the priority status of all the applicants no matter the flow or complexity of movement. For this analysis the information on each applicant's priority was taken from their first observation so any changes in priority rating are not taken into account.

The table shows that over this 29 month observation period a higher proportion of applicants were housed who were A ( $66.3 \%$ of the total classified as A were housed) and B priority ( $40.3 \%$ ) compared with C ( $18.7 \%$ ) and D (11.9\%) priority. Conversely, a higher proportion of C (41.2\%) and D (42.1\%) priority applicants exited the waiting list than did A (18.3\%) and B ( $30.8 \%$ ). We would expect these differences to become more pronounced if these populations were followed for a longer period of time.

Table 8.3: Movement of the applicants through the various states at June 2005.

| Types of Applicant Flows | Number of <br> Households | Percent of <br> Households | Average <br> annual <br> numbers |
| :--- | :---: | :---: | :---: |
| Three simplest flows: | 8537 | 22.8 | 3532.6 |
| APPL | 11770 | 31.4 | 4870.3 |
| APPL - TNNT | 13048 | 34.8 | 5399.1 |
| APPL - Exit W.L. | 2148 |  |  |
| More complex flows: | 1110 | 3.7 | 888.8 |
| APPL - with moves on and off W.L. | 107 | 0.0 | 459.3 |
| APPL with moves on and off W.L. - TNNT | 68 | 0.2 | 44.3 |
| APPL - TNNT - APPL with moves on and off W.L. | 417 | 1.1 | 172.1 |
| APPL-TNNT-APPL-TNNT | 276 | 0.7 | 114.2 |
| TNNT-APPL with moves on and off W.L. | 37481 | 100.0 | 15509.4 |
| TNNT- APPL with moves on and off W.L. - TNNT |  |  |  |
| Total |  |  |  |

Table 8.4: Priority status of the applicants for the three simplest flows ${ }^{1}$ at June 2005

| Priority | APPL only |  | APPL - EXIT |  | APPL - TNNT |  | All APPL no matter <br> what flow |  |
| :--- | :---: | ---: | :---: | ---: | ---: | ---: | ---: | ---: |
|  | Number | Percent | Number | Percent | Number | Percent | Number | Percent |
| A | 156 | 1.8 | 340 | 2.6 | 1233 | 10.5 | 1860 | 5.0 |
| B | 3390 | 39.7 | 5962 | 45.7 | 7799 | 66.3 | 19352 | 51.6 |
| C | 3369 | 39.5 | 4862 | 37.2 | 2207 | 18.8 | 11799 | 31.5 |
| D | 1622 | 19.0 | 1884 | 14.4 | 531 | 4.5 | 4470 | 11.9 |
| Total | 8537 | 100.0 | 13048 | 100.0 | 11770 | 100.0 | 37481 | 100.0 |

1 Note this is using the first applicant observation and does not investigate whether the priority level has changed over multiple applicant observations.

### 8.4 Reasons for applicants exiting the waiting list

Table 8.5 shows the reasons for the applicant exits using the HNZC codes. The majority (three quarters) of exits are recorded as an "Exit no response". This category includes applicants who had not responded to an application review request and who could not be contacted after multiple attempts to reach them using all know contact details. It also includes those applicants who did not verify their circumstances with the required documentation. In the remaining quarter of cases applicants were removed from the waiting list at the request of the applicant.

Table 8.5: Reasons for exiting for all applicant exit records ${ }^{1}$

| Exit <br> Code | Reason | Number of <br> Households | Percentage of <br> Households | Annually Rate |
| :--- | :--- | :---: | :---: | :---: |
| XHN | Exit no response | 10225 | 72.0 | 4231.0 |
| XAC | Appl cancelled by | 3806 | 26.7 | 1574.9 |
| Customer | Ineligible income/assets | 164 | 1.2 | 67.8 |
| XCM | Exit to Case | 7 | 0.1 | 2.9 |
| XHR | Management |  |  |  |
| Ineligible residency | 4 | 0.0 | 1.6 |  |
| Total |  | 14026 | 100.0 | 5803.9 |

1 If there was more than one exit per household only the first exit was considered for this analysis.

## 9 Hospitalisations in housing applicants and tenants

This section provides an analysis of hospitalisations in the cohort of housing applicants and housing tenants compared with New Zealanders not identified as members of the cohort population (other NZ). The first part of this section describes the effects of different approached used to filter the hospitalisation data before more detailed analysis (as described in the methods section). The second part presents the results of the analysis of these filtered data.

### 9.1 Analytical steps in interpreting hospitalisation data

### 9.1.1 Removing non-hospitalisations and overseas visitors

This initial filtering (Table 9.1) removes events that have been entered for administrative reasons and therefore do not reflect disease events in the subject population. Overseas visitors are also removed as they are not part of the denominator population. This step takes out about $11 \%$ of events in the cohort (applicant and tenant) population.

Table 9.1: ‘Non-hospitalisation’ events filtered out of hospitalisation data, May 2003 to June 2005

| Event type | Cohort population |  | Other NZ Population |  |
| :--- | ---: | ---: | ---: | ---: |
|  | Average <br> annual <br> numbers | Percent <br> $(\%)$ | Average <br> annual <br> numbers | Percent <br> $(\%)$ |
| Transfers | 3636.5 | 4.46 | 47046.0 | 6.26 |
| Boarders | 493.4 | 0.61 | 3948.0 | 0.53 |
| Cancelled operations | 595.8 | 0.73 | 5261.1 | 0.70 |
| Well babies | 2549.5 | 3.13 | 35461.4 | 4.72 |
| Error DRGs | 165.2 | 0.20 | 1215.2 | 0.16 |
| Overseas patients | 1694.8 | 2.08 | 18381.7 | 2.45 |
| Remainder | 72587.1 | 89.01 | 642145.8 | 85.44 |
| Total | 81545.5 | 100.22 | 751536.9 | 100.26 |

Total adds up to $>100 \%$ because some events are removed for more than one reason

### 9.1.2 Selecting admission types

Most analyses of hospitalisation data need to focus on specific types of hospital admission as described in the methods section. This section divides hospital events into the following categories:

- Acute admissions, being unplanned admission on the day of presentation at the healthcare facility. These can be divided into:
- Emergency Department. (ED) admissions being acute cases seen in the emergency department and sent home on the same day
- Other acute admissions
- Arranged admissions, being planned admission <7days after the decision was made that the admission was necessary
- Waiting list admissions, being planned admissions with an admission date 7 days or more from assessment,
- Other admissions included elective admission to private hospitals and psychiatric patients returning from leave after >10 days

The distribution of hospitalisations according to these categories is show in Table 9.2. As these data show, about $56 \%$ of cohort admissions are recorded as acute. Specific groups of acute admissions include emergency department acute admissions ( $7.0 \%$ of total admissions in cohort population), and day acute admissions (14.0\%). Arranged admissions also include both day cases and overnight admissions in about equal proportions.

## Table 9.2: Hospitalisations classified according to admission types, May 2003 to June 2005 (Filtered to exclude non hospitalisations and overseas cases)

| Classification by admission type | Cohort population |  | Other NZ population |  |
| :--- | ---: | ---: | ---: | ---: |
|  | Average <br> annual <br> numbers | Percent <br> $(\%)$ | Average <br> annual <br> numbers | Percent <br> $(\%)$ |
| ED Acute admissions | 5083.4 | 7.0 | 33336.0 | 5.2 |
| Other Acute admission | 35928.9 | 49.5 | 311742.9 | 48.5 |
| Arranged admission | 20069.5 | 27.6 | 154637.5 | 24.1 |
| Waiting list admission | 11485.4 | 15.8 | 142146.5 | 22.1 |
| Other admission | 19.8 | 0.0 | 282.9 | 0.0 |
|  |  |  |  |  |
| Total | 72587.1 | 100 | 642145.8 | 100 |
| Day acute | 10137.7 | 14.0 | 76317.7 | 11.9 |
| Other acute | 30797.1 | 42.4 | 268107.2 | 41.8 |
|  |  |  |  |  |
| Day arranged | 10441.8 | 14.4 | 71009.5 | 11.1 |
| Other arranged | 9627.7 | 13.3 | 83628.0 | 13.0 |

The use of these categories does not appear consistent across DHBs as shown for the cohort population in Figure 9.1 (and Table 12.2 in the appendix) and for the other NZ population in Figure
9.2(and

Table 12.3 in the appendix). In particular, district health boards (DHB) in the northern half of the North Island as well as Whanganui and Otago tend to record emergency department cases in the NMDS whereas other DHB do not. Other categories, such as arranged and waiting list admissions, also make up variable proportions of recorded hospitalisations for different DHB. The implications of including or excluding these different categories of hospitalisations will be explored further using a sensitivity analysis of the study findings.

The majority of the analyses reported here will include acute and arranged admissions on the basis that these admissions correspond in time to disease or injury onset or exacerbation. Waiting list events, on the other hand, are considered to be more strongly influenced by health service factors so are excluded from the main analyses.

Figure 9.1: Distribution of admission types across DHBs for cohort population (applicants and tenants), May 2003 to June 2005

Figure 9.2: Distribution of admission types across DHBs for other NZ population, May2003 to June 2005

### 9.1.3 Select whether to include principal and additional diagnosis

Patients may be discharged with up to 20 diagnostic codes recorded. As Table 9.3 shows, about three quarters of patients are discharged with a principal and one or more additional diagnoses. There are circumstances where it is useful to count a condition when the clinical code appears as an additional diagnosis as well as the principal diagnosis. The analysis reported here will use only the principal diagnosis.

Table 9.3: Number of diagnostic codes recorded for hospitalised cases, May 2003 to June 2005 (Filtered to exclude non hospitalisations, overseas visitors and waiting list admissions)

| Number of <br> diagnostic codes | Cohort population |  | Other NZ population |  |
| :--- | ---: | ---: | ---: | ---: |
|  | Average annual <br> numbers | $(\%)$ | Average annual <br> numbers | $(\%)$ |
| 1 | 16121.5 | 22.2 | 221244.5 | 29.4 |
| 2 | 21389.1 | 29.5 | 198708.9 | 26.4 |
| 3 | 13284.5 | 18.3 | 116499.2 | 15.5 |
| 4 | 7267.4 | 10.0 | 70618.2 | 9.4 |
| 5 | 4674.5 | 6.4 | 45617.1 | 6.1 |
| 6 | 3076.2 | 4.2 | 30199.4 | 4.0 |
| 7 | 2082.5 | 2.9 | 20734.6 | 2.8 |
| 8 | 1432.6 | 2.0 | 14175.2 | 1.9 |
| 9 | 982.2 | 1.4 | 9927.7 | 1.3 |
| $10+$ | 2276.8 | 3.1 | 23699.1 | 3.2 |
|  |  |  |  |  |
| Total | 72587.1 | 100 | 751423.8 | 100 |

### 9.1.4 Selecting and removing irrelevant hospitalisations

Table 9.4 shows conditions that could be excluded from some analyses. These include sameday diagnostic procedures and same-day treatment of chronic conditions, which account for 9.7 $\%$ of the hospitalisation events (of the acute and arranged admission in the cohort population). A further $18.4 \%$ of maternity and $2.2 \%$ perinatal events and $1.5 \%$ of disability support service (DSS) admissions could also be removed. These excluded events are collectively called irrelevant conditions for the purpose of this research.

Table 9.4: Selected irrelevant conditions, May 2003 to June 2005 (filtered to exclude non hospitalisations, overseas visitors and waiting list admissions)

| Classification by functional group | Cohort population |  | Other NZ population |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Average annual numbers | Percent <br> (\%) | Average annual numbers | Percent (\%) |
| 'Same day' diagnostic procedures <br> - Colposcopies <br> - Cystoscopies <br> - ERCPs <br> - Colonoscopies <br> - Gastroscopies <br> - Bronchoscopies <br> - Overnight sleep apnoea testing <br> Total |  0.5 <br>  7.4 <br>  12.0 <br>  25.8 <br>  18.5 <br>  67.4 <br>  98.3 <br>   <br> 229.8  |  0.00 <br>  0.01 <br>  0.02 <br>  0.04 <br>  0.03 <br>  0.11 <br>   <br>  0.16 <br>   | 28.6  <br> 180.0  <br> 238.6  <br> 455.5  <br> 397.8  <br>  723.7 <br>  609.2 <br>   <br> 2633.5  |  0.01 <br>  0.04 <br>  0.05 <br>  0.09 <br>  0.08 <br>  0.14 <br>   <br>  0.12 <br>   <br> 0.5  |

### 9.1.5 Select whether to include repeat admissions

Table 9.5 shows the frequency of hospitalisations in this cohort during the 26-month observation period. As this analysis demonstrates, about $20.3 \%$ of the cohort population were recorded as being admitted to hospital during their time in the cohort (already filtered to exclude non hospitalisations, overseas visitors and waiting list admissions and irrelevant conditions). A significant minority of cohort members ( $7.1 \%$ ) had 2 or more hospitalisations recorded. Some of these admissions would have been readmissions for continuing treatment of the same disease or injury episode. The following analysis (Table 9.6) explores the effect of using different readmission filters. These filters range from narrow readmission exclusions (e.g. same 3 -character principal clinical code within one month) to wide exclusions (e.g. same principal or additional clinical code within 12 months).
Most of the analyses reported here will use a one-month filter based on the same individual (NHI number) readmitted with the same 3-character ICD. 10 diagnostic code recorded as the
principal diagnosis. This filter is chosen on the basis that a high proportion of such events represent continuing treatment of the same disease or injury episode. These admissions are therefore strongly influenced by factors such as the initial severity of the illness or injury, the method and effectiveness of treatment, and patient compliance and response. These factors have little relationship to the research hypotheses under investigation.

Table 9.5: Frequency of admissions, June 2003 to May 2005 (filtered to exclude non hospitalisations, overseas visitors and waiting list admissions and irrelevant conditions)

| Hospitalisation <br> count | Cohort population |  | Other NZ population |  |
| ---: | ---: | ---: | ---: | ---: |
|  | Number |  | $(\%)$ | Number |
|  | $(\%)$ |  |  |  |
| 0 | 192264 | 79.7 | 3002741 | 85.90 |
| 2 | 31911 | 13.2 | 343875 | 9.84 |
| 3 | 9123 | 3.8 | 86067 | 2.46 |
| 4 | 3523 | 1.5 | 30540 | 0.87 |

### 9.1.6 Select conditions of interest

The next section (9.2) presents results for a range of conditions of interest.

### 9.1.7 Calculate disease rates - Duration of time in cohort

The first step in this process is to calculate the duration of person-time in the cohort. The analyses in this section record the person time subjects contribute as applicants or tenants over the observation period (June 2003 to May 2005). Subjects can only be contributing to the study (i.e. recorded as having a hospitalisation or adding person time to the study denominator) while they are known to be a housing applicant or housing tenant.

Encrypted NHI numbers were used to identify unique individuals. As expected, this analysis identified many individuals with multiple inclusions in HNZC datasets corresponding to being applicants and tenants. In a relatively small proportion ( $14.1 \%$ ), these periods overlapped. These situations are summarised in Table 9.7.

Some of these patterns have implications for how the events and person-time are treated, as described below:

- The person was recorded as a housing applicant then became a tenant while still being recorded as an applicant (\#1). Time as a tenant retained, but time as an applicant removed while any overlap occurred.
- The person was recorded as a tenant then became a housing applicant while still being recorded as a tenant (\#2). Time as a tenant retained, but time as an applicant removed while any overlap occurred.
- The person was included in two applications at the same time (\#3a). Second application was assumed to supersede first which was exited at the time the second application was made.
- A subset of these overlapping applications are those with the same start date (\#3b). Because it is difficult to know which application to assign the person to, these subjects are excluded.
- The person was included in three or more applications at the same time (\#4). These subjects are excluded from the study because of the high level of uncertainty around which household to assign them to.
- The person was included in two tenancies at the same time (\#5a). The second tenancy was assumed to supersede the first, which was exited at the time the second tenancy, started.
- A subset of these overlapping tenancies are those with the same start and finish date (\#5b). Because it is difficult to know which tenancy to assign the person to, these subjects are excluded.
- A further subset of these overlapping tenancies are those where one is included within the other i.e. the second one has a later start date and an earlier finish date than the other ( $\# 5 \mathrm{c}$ ). Because it is difficult to know which tenancy to assign the person to, these subjects are excluded.
- The person was simultaneously included in three or more tenancies(\#6). These subjects are excluded from the study because of the high level of uncertainty around which household to assign them to.
- The person was simultaneously included in a mix of multiple applications and tenancies (\#7). These subjects are excluded from the study because of the high level of uncertainty around which household to assign them to.

Collectively, these exclusions resulted in the loss of $6.7 \%$ of individuals recorded in the cohort population (Table 9.7). It is likely that at least some of these apparent overlaps are caused by the care of shared custody children who may be recorded as members of two different households simultaneously. This filtering removed $12.5 \%$ of shared custody children, $7.0 \%$ of other children and $6.1 \%$ of adults.

Table 9.7: Number of individuals in cohort with overlapping time spent as housing
applicants and tenants, May 2003 to June 2005 (based on total HNZC data)

*Indicates categories excluded from the analysis

After applying these data editing principles, the duration of time in the cohort was subsequently analysed, with results shown in Table 9.8. As these data show, the mean duration of time as an applicant was 229 days, and as a tenant was 639 days during this 26 months (total 792 days) observation period (from June 2003 to May 2005).

Table 9.8: Summary statistics for duration of time in cohort, May 2003 to June 2005 (with adjustment for applicants and tenants with overlapping periods)

| Summary Statistics | Applicants | Tenants | Total |
| :--- | :---: | :---: | ---: |
| N | 75159 | 192527 | 238271 |
| Mean | 229.3 | 638.7 | 587.6 |
| Min | 1 | 1 | 1 |
| Lower Quartile | 70 | 489 | 364 |
| Median | 151 | 792 | 792 |
| Upper Quartile | 330 | 792 | 792 |
| Max | 792 | 792 | 792 |

### 9.2 Characteristics of hospitalisations

### 9.2.1 Hospitalisation rates in housing applicants, tenants and other NZ population

The following graph (Figure 9.3) and tables in the appendix (Table 12.4, Table 12.5) show hospitalisation numbers and rates for housing applicants, housing tenants and the other NZ population based on different categories of hospitalisation and filtering approaches.

- Total Contacts $=$ Total hospital contacts recorded in NMDS dataset
- Hosps $=$ Hospitalisations, being total contacts minus non-hospitalisations and overseas visitors
- Acute and Arranged = Hospitalisations minus waiting list cases
- Acute $=$ Hospitalisations minus arranged and waiting list cases
- Acute Ex ED = Acute hospitalisations minus emergency department cases
- Overnight Hosps = Acute hospitalisations minus day cases
- Relevant Hosps = Acute and arranged hospitalisations minus 'irrelevant hospitalisations' (see list of irrelevant conditions Table 9.4)
- Standard Hosps = Relevant Hosps excluding one-month readmissions (those readmitted with the same 3-character ICD. 10 principal diagnosis within one month)

This analysis confirms that the cohort population (applicants and tenants) have markedly higher rates of hospital contact for all categories of event than the other $N Z$ population. Similarly, housing applicants have higher hospitalisation rates than housing tenants for all categories of hospitalisation.

Figure 9.3: Annual age-standardised hospitalisation rates in housing applicants and housing tenants, compared with the other $N Z$ population, according to major admission categories, May 2003 to June 2005

The subsequent analyses in this section will focus on analysis based on the 'standard hosps' population shown in (Figure 9.3) which has the following characteristics:

- Based on principal diagnosis.
- Excludes non-hospitalisations and overseas visitors ( $\sim 11 \%$ of events) - See description in previous section (Table 9.1), for these events.
- Excludes waiting list cases ( $\sim 16 \%$ of remaining events) - This category of event strongly reflects availability of hospital services.
- Excludes 'irrelevant conditions' ( $\sim 32 \%$ of remaining events) - This category included events that are determined by patterns of child-bearing (maternity and perinatal events) and by access and use of specific day-patient diagnostic and treatment services (particularly renal dialysis).
- Excludes readmissions within one month ( $\sim 5 \%$ of remaining events) - Most of these events reflect continuing care of the same incident episode of illness or injury. They are likely to be strongly influenced by health service factors and patient compliance.
- This leaves $50 \%$ of total hospital events in the cohort population (see Table 12.4 and Table 12.5 for exact numbers).

In addition, this analysis also excludes a proportion of subjects, being

- Those HNZC applicants and tenants who could not be matched with an NHI number ( $\sim 8 \%$ ). See section 4.3.1.
- Subjects whose time in the cohort could not be accurately assigned to specific applicant or tenant households ( $\sim 7 \%$ of total subjects). See section 9.1.7.

This analysis will work through the following sequence:

- Characteristics of those hospitalised.
- Comparison of age-standardised rates of hospitalisation among housing applicants, housing tenants and the other $N Z$ population.
- Analysed by major ICD. 10 chapters.
- Analysed by selected diseases.
- Comparison of age-ethnicity standardised rates of hospitalisation among housing applicants, housing tenants and other NZ population.
- Analysed by major ICD. 10 chapters.
- Analysed by selected diseases.
- Hospitalisation rates according to time as a HNZC tenant
- Comparison of housing applicants (who will later became tenants) with housing tenants during their first year as tenants.
- Comparison of housing applicants with housing tenants who have been re-housed for varying lengths of time for selected diseases.
- Sensitivity analysis to test the effects of different assumptions.
- Restricting analysis to overnight admissions.

### 9.2.2 Characteristics of those hospitalised

This section reports on hospitalisation rates of housing applicants, housing tenants and the other NZ population, according to person, place and time characteristics. The main focus of this analysis has been on hospitalisations identified by applying the 'standard' filter (removes overseas, non-hospitalisations, waiting list cases, irrelevant conditions, and those readmitted within one-month with the same condition).

- These results are shown graphically by age (Figure 9.4), sex (Figure 9.5) and ethnicity (Figure 9.6).
- An indication of socio-economic position of individual households can be obtained from their equivalised income (Figure 9.7). HNZC provides the Statistical Area Unit (SAU codes) of their properties. This SAU code can be used to assign a deprivation level (NZDep2001 ${ }^{4}$ ) to each area which provides an indication of the socioeconomic position of the neighbourhood (Figure 9.8). Hospitalisation rates can be calculated according to the deprivation level (Figure 9.9).
- HNZC provides HNZC region codes with its data. The SAU codes allow the urban-rural distribution of housing tenants to be assigned (Figure 9.10) and hospitalisation rates calculated according to urban-rural classification (Figure 9.11).
- This analysis has also looked at hospitalisation rates according to year and season (Figure 9.13).
- Results are also tabulated in the appendix (Table 12.7 to Table 12.14)
- This analysis has also been carried out for total hospital contacts, as a comparison with the filtered results (Table 12.6).

This analysis shows the following:

- The cohort population (applicants and tenants) have significantly higher hospitalisation rates than the other NZ population for all age groups, and for males and females. They also have higher rates for European, Maori and Pacific people. However, this is not the case for those of "Other ethnicity" and "Not Stated" ethnicity. Rates for these populations have been distorted because of the way in which ethnicity information is gathered for these groups (see 4.4.2). One consequence is that the denominator population used to calculate the rates

[^4]for those of "Other ethnicity", in the other NZ population is artificially small, resulting in the excessively high rate calculated for this population (Figure 9.6).

- Housing applicants had a higher overall hospitalisation rate than housing tenants. This relationship also applied for most age groups (except for children 5-9 years and those aged $60+$ ), for males and females, and for European, Maori and Pacific people. Amongst those of Asian ethnicity, hospitalisation rates appeared highest among housing tenants.
- Surprisingly, hospitalisation rates were significantly higher for the highest income quintile of housing applicants and lowest for the lowest income quintile. By contrast, there was a slight negative gradient for housing tenants with higher income associated with a lower hospitalisation rate.
- Similarly, there was a modest increase in hospitalisation rates for housing tenants living in the most deprived neighbourhoods where these properties are concentrated ( $42 \%$ are in NZDep 2001 category 10). Rates for NZDep 1 and 2 are based on very small numbers.
- There are significant regional differences in hospitalisation rates for both housing applicants and housing tenants. Hospitalisations rates are particularly high for housing applicants in the Northern HNZC region.
- A disproportionate number of HNZC properties are in urban areas (particularly main urban areas) compared with rural areas. Hospitalisations rates are lower for those in satellite urban areas, and non-significantly higher in rural areas.
- Hospitalisations follow a familiar seasonal pattern with higher rates in winter, particularly for housing applicants.

### 9.2.3 Comparison of hospitalisation rates by major disease categories

This section presents an analysis of hospitalisations according to the major ICD. 10 category of their principal diagnosis. Hospitalisation rates were calculated and age-standardised to the population structure of NZ at the time of the 2001 census. These analyses again used the standard filter (based on principal diagnosis with exclusion of non-hospitalisations, overseas visitors, waiting-list admissions, irrelevant conditions and one-month readmissions).

These results are presented in graphical and tabular form.

- Age-standardised disease rates according to broad ICD. 10 categories (Figure 9.14)
- A comparison of hospitalisation rates in the cohort population compared with the other NZ population (Figure 9.15, Table 12.15).
- A comparison of hospitalisation rates in housing applicants compared with housing tenants (Figure 9.16, Table 12.16).

Figure 9.14: Hospitalisation age-standardised rates in housing applicants and housing tenants, compared with the other $N Z$ population, according to major disease categories, May 2003 to June 2005

These comparisons (Figure 9.15) show that the cohort population (housing applicants and tenants combined) have significantly higher hospitalisation rates that the other NZ population for all major disease categories except congenital diseases. By contrast, hospitalisation rates for housing applicants and housing tenants were similar for major disease categories (Figure 9.16) except for mental and behavioural disorders, diseases of the ear and mastoid and congenital conditions where housing applicants had significant higher rates of hospitalisation than housing tenants. There were also disease categories where housing applicants had significantly lower hospitalisation rates than tenants, notably for neoplasms and skin and subcutaneous diseases.

Figure 9.15: Hospitalisation age-standardised rate ratios in cohort population (applicants and tenants) compared with other $N Z$ population, according to major disease categories, May 2003 to June 2005

Figure 9.16: Hospitalisation age-standardised rate ratios in housing applicants compared with housing tenants, according to major disease categories, May 2003 to June 2005

### 9.2.4 Comparison of hospitalisation rates by selected diseases

This section presents an analysis of hospitalisations according to selected diseases, based on their principal diagnosis. Hospitalisation rates were calculated and age-standardised to the population structure of NZ at the time of the 2001 census. These analyses again used the standard filter (based on principal diagnosis with exclusion of non-hospitalisations, overseas visitors, waiting-list admissions, irrelevant conditions and one-month readmissions).

These results are again presented in graphical and tabular form.

- A comparison of hospitalisation rates in the cohort population compared with the other NZ population (Table 12.17).
- A comparison of hospitalisation rates in housing applicants compared with housing tenants (Table 12.18)
- Graphical presentation of disease rates and relative risks based on functional groupings of diseases.

## Infectious diseases

The following figures show age-standardised rates of hospitalisation for important infectious diseases and groups of diseases.

- The first figure (Figure 9.17) shows hospitalisation rates for housing applicants, housing tenants and the other $N Z$ population.
- The second figure (Figure 9.18) shows age-standardised rate ratios in cohort population (applicants and tenants) compared with other $N Z$ population.
- The third figure (Figure 9.22) shows age-standardised rate ratios in housing applicants compared with housing tenants.

This analysis shows the following:

- Some of these diseases are uncommon causes of hospitalisation in New Zealand, so it is hard to draw conclusions from the data presented here (notably hepatitis A, hepatitis B, mumps).
- For most of the specific infectious diseases and groups of diseases analysed, hospitalisation rates were marked and significantly higher in the cohort population compared with the other $N Z$ population. The only exceptions were pertussis, which had the same rates in both, and the category of other viral infection of skin and membranes, which had a nonsignificantly higher rate in the cohort population. Diseases which seemed particularly concentrated in the cohort population were tuberculosis, hepatitis $A$ and Hepatitis $B$ where rates were $>3$ times higher that in the other $N Z$ population.
- When comparing rates between housing applicants and housing tenants, rates were fairly similar. There was a lower rate of other septicaemia in the housing applicants though this was statistically marginal.

Figure 9.17: Hospitalisation age-standardised rates in housing applicants and housing tenants, compared with other $N Z$ population, for selected infectious diseases, May 2003 to June 2005

Figure 9.18: Hospitalisation age-standardised rate ratios in cohort population (applicants and tenants) compared with other $N Z$ population, according to selected infectious diseases, May 2003 to June 2005

Figure 9.19: Hospitalisation age-standardised rate ratios in housing applicants compared with housing tenants, according to selected infectious diseases, May 2003 to June 2005

## Respiratory infections and asthma

The following figures show age-standardised rates of hospitalisation for important respiratory infections and asthma.

- The first figure (Figure 9.20) shows hospitalisation rates for housing applicants, housing tenants and the other $N Z$ population.
- The second figure (Figure 9.21) shows age-standardised rate ratios in cohort population (applicants and tenants) compared with other $N Z$ population.
- The third figure (Figure 9.22) shows age-standardised rate ratios in housing applicants compared with housing tenants.

This analysis shows the following:

- For almost all of these respiratory diseases, hospitalisation rates were marked and significantly higher in the cohort population compared with the other $N Z$ population. The only exception was acute laryngitis, tracheitis and epiglottitis, which had a nonsignificantly higher rate. Diseases which seemed particularly concentrated in the cohort population were bronchitis and other chronic obstructive pulmonary disease where rates were $>3$ times higher than in the other $N Z$ population.
- When comparing rates between housing applicants and housing tenants, rates were fairly similar except for four diseases where rates were significantly higher: acute pharyngitis, acute bronchitis, acute bronchiolitis, and asthma.

Figure 9.20: Hospitalisation age-standardised rates in housing applicants and housing tenants, compared with other NZ population, for selected respiratory diseases, May 2003 to June 2005

Age-standardised Hospitalisation Rates (cases/100 000/yr)

Figure 9.21: Hospitalisation age-standardised rate ratios in cohort population (applicants and tenants) compared with other $N Z$ population, according to selected respiratory diseases, May 2003 to June 2005

Figure 9.22: Hospitalisation age-standardised rate ratios in housing applicants compared with housing tenants, according to selected respiratory diseases, May 2003 to June 2005

Age-standardised Rate Ratios

## Skin and bone infections

The following figures show age-standardised rates of hospitalisation for important skin and bone infections.

- The first figure (Figure 9.23) shows hospitalisation rates for housing applicants, housing tenants and the other NZ population.
- The second figure (Figure 9.24) shows age-standardised rate ratios in cohort population (applicants and tenants) compared with other NZ population.
- The third figure (Figure 9.25) shows age-standardised rate ratios in housing applicants compared with housing tenants.

This analysis shows the following:

- For all of these skin and bone infections, hospitalisation rates were marked and significantly higher in the cohort population compared with the other NZ population. A disease which seemed particularly concentrated in the cohort population was impetigo where rates were $>3$ times higher than in the other $N Z$ population.
- When comparing rates between housing applicants and tenants, rates were generally lower in housing applicants compared with housing tenants, but this difference was only statistically significant for cutaneous abscess, furuncle and carbuncle.

Figure 9.23: Hospitalisation age-standardised rates in housing applicants and housing tenants, compared with other NZ population, for selected skin and bone infections, May 2003 to June 2005

Figure 9.24: Hospitalisation age-standardised rate ratios in cohort population (applicants and tenants) compared with other $N Z$ population, according to selected skin and bone infections, May 2003 to June 2005

Age-standardised Rate Ratios

Figure 9.25: Hospitalisation age-standardised rate ratios in housing applicants compared with housing tenants, according to selected skin and bone infections, May 2003 to June 2005

## Other diseases with partly infectious causes

The following figures show age-standardised rates of hospitalisation for other diseases that are thought to have an infectious cause.

- The first figure (Figure 9.26) shows hospitalisation rates for housing applicants, housing tenants and the other $N Z$ population.
- The second figure (Figure 9.27) shows age-standardised rate ratios in cohort population (applicants and tenants) compared with other NZ population.
- The third figure (Figure 9.28) shows age-standardised rate ratios in housing applicants compared with housing tenants.

This analysis shows the following:

- For most of these diseases, hospitalisation rates were marked and significantly higher in the cohort population compared with the other NZ population. Exceptions were inflammatory diseases of the CNS and polyneuropathies where rates were only slightly higher in the cohort population. Acute rheumatic fever was particularly concentrated in the cohort population where rates that were $>3$ times higher than in the other $N Z$ population.
- When comparing rates between housing applicants and housing tenants, rates were fairly similar for all conditions.

Figure 9.26: Hospitalisation age-standardised rates in housing applicants and housing tenants, compared with other $N Z$ population, for selected acute and chronic diseases with partly infectious origins, May 2003 to June 2005

Figure 9.28: Hospitalisation age-standardised rate ratios in housing applicants compared with housing tenants, according to selected acute and chronic diseases with partly infectious origins, May 2003 to June 2005

Age-standardised Rate Ratios

## Cardiovascular diseases

The following figures show age-standardised rates of hospitalisation for important cardiovascular diseases.

- The first figure (Figure 9.29) shows hospitalisation rates for housing applicants, housing tenants and the other $N Z$ population.
- The second figure (Figure 9.30) shows age-standardised rate ratios in cohort population (applicants and tenants) compared with other $N Z$ population.
- The third figure (Figure 9.31) shows age-standardised rate ratios in housing applicants compared with housing tenants.

This analysis shows the following:

- For all of these cardiovascular diseases, hospitalisation rates were marked and significantly higher in the cohort population compared with the other $N Z$ population.
- When comparing rates between housing applicants and housing tenants, rates were fairly similar for all conditions.

Figure 9.29: Hospitalisation age-standardised rates in housing applicants and housing tenants, compared with other $N Z$ population, for selected cardiovascular diseases, May 2003 to June 2005

Age-standardised Hospitalisation Rates (cases/100 000/yr)

Figure 9.31: Hospitalisation age-standardised rate ratios in housing applicants compared with housing tenants, according to selected cardiovascular diseases, May 2003 to June 2005

## Mental and behavioural disorders

The following figures show age-standardised rates of hospitalisation for all categories of mental and behavioural disorders.

- The first figure (Figure 9.32) shows hospitalisation rates for housing applicants, housing tenants and the other $N Z$ population.
- The second figure (Figure 9.33) shows age-standardised rate ratios in cohort population (applicants and tenants) compared with other $N Z$ population.
- The third figure (Figure 9.34) shows age-standardised rate ratios in housing applicants compared with housing tenants.

This analysis shows the following:

- For most categories of mental and behavioural disorders, hospitalisation rates were marked and significantly higher in the cohort population compared with the other $N Z$ population. Exceptions were behavioural syndromes, mental retardation, and disorders of psychological development, disorders of childhood and adolescence and unspecified mental disorders where rates were not significantly different. Mental disorders which seemed particularly concentrated in the cohort population were schizophrenia and other delusional disorders, manic episode or bipolar disorder, and adult personality disorder where rates were $>3$ times higher than in the other $N Z$ population.
- When comparing rates between housing applicants and housing tenants, hospitalisation rates were marked and significantly higher in the housing applicants for most categories of mental and behavioural disorders.

Figure 9.32: Hospitalisation age-standardised rates in housing applicants and housing tenants, compared with other $N Z$ population, for categories of mental and behavioural disorders, May 2003 to June 2005

Age-standardised Hospitalisation Rates (cases/100 000/yr)

Figure 9.34: Hospitalisation age-standardised rate ratios in housing applicants compared with housing tenants, according to categories of mental and behavioural disorders, May 2003 to June 2005

Age-standardised Rate ratios

Injuries and poisonings and external causes occurring at home
These categories of hospitalisation differ from others included in this analysis in two respects:

- External causes are an additional classification to that used for principal diagnosis. An individual hospitalisation event, particularly one for injury or poisoning (S00-T98), may also be assigned an " $E$ " code (V01-Y98).
- Where an "E" code is assigned in the range W00-Y34 (except Y06 and Y07), then a place of occurrence code is also assigned. This code allows injuries in the home to be distinguished from other injuries.

The following figures show age-standardised rates of hospitalisation for important injuries and poisonings.

- The first figure (Figure 9.35) shows hospitalisation rates for housing applicants, housing tenants and the other $N Z$ population for all categories of injury and poisoning. The second figure (Figure 9.36) shows these rates for the most common specified injuries and poisonings.
- The third figure (Figure 9.37) shows age-standardised rate ratios in cohort population (applicants and tenants) compared with other $N Z$ population for all categories of injury and poisoning. The forth figure (Figure 9.38) shows these rates for the most common specified injuries and poisonings.
- The fifth figure (Figure 9.39) shows age-standardised rate ratios in housing applicants compared with housing tenants for all categories of injury and poisoning. The sixth figure (Figure 9.40) shows these rates for the most common specified injuries and poisonings.

This analysis shows the following:

- For most categories of injury and poisoning, hospitalisation rates were marked and significantly higher in the cohort population compared with the other NZ population. Exceptions were injuries to hip and thigh. Amongst specific common injuries, rates were higher in the cohort population for open would of head, intracranial injury, open wound of wrist and hand, fracture of wrist and hand, superficial injury of lower leg and complications of procedures. Rates were less for fractures of the forearm and fracture of femur.
- When comparing rates between housing applicants and housing tenants, hospitalisation rates were similar for most categories of injury and poisoning and for specific common injuries. The only exceptions were significantly higher hospitalisation rates in the housing applicants for poisonings and toxic effects and significantly lower rates for injuries to shoulder and upper arm.

Figure 9.35: Hospitalisation age-standardised rates in housing applicants and housing tenants, compared with other NZ population, for all categories of injury and poisonings, May 2003 to June 2005

Figure 9.36: Hospitalisation age-standardised rates in housing applicants and housing tenants, compared with other $N Z$ population, for specific common injuries and poisonings, May 2003 to June 2005

Figure 9.37: Hospitalisation age-standardised rate ratios in cohort population (applicants and tenants) compared with other $N Z$ population, for all categories of injury and poisonings, May 2003 to June 2005

Figure 9.38: Hospitalisation age-standardised rate ratios in cohort population (applicants and tenants) compared with other $N Z$ population, for specific common injuries and poisonings, May 2003 to June 2005

Figure 9.39: Hospitalisation age-standardised rate ratios in housing applicants compared with housing tenants, for all categories of injury and poisonings, May 2003 to June 2005

Figure 9.40: Hospitalisation age-standardised rate ratios in housing applicants compared with housing tenants, for specific common injuries and poisonings, May 2003 to June 2005

The following figures show age-standardised rates of hospitalisation for important external causes ( E codes) of injuries and poisonings.

- The first figure (Figure 9.41) shows hospitalisation rates for housing applicants, housing tenants and the other $N Z$ population for all categories of external causes. The second figure (Figure 9.42) shows these rates for selected external causes and the third (Figure 9.43) for common external causes.
- The fourth figure (Figure 9.44) shows age-standardised rate ratios in cohort population (applicants and tenants) compared with other $N Z$ population for all categories of injury and poisoning. The fifth figure (Figure 9.45) shows these rates for selected external causes and the sixth (Figure 9.46) for common external causes.
- The seventh figure (Figure 9.56) shows age-standardised rate ratios in housing applicants compared with housing tenants for all categories of external cause. The eighth figure (Figure 9.48) shows these rates for selected external causes and the ninth (Figure 9.49) for the most common external causes.

This analysis shows the following:

- For most categories of external cause, hospitalisation rates were marked and significantly higher in the cohort population compared with the other $N Z$ population. Exceptions were drowning and submersion, other accidental threats to breathing, exposure to electricity and extreme temperature, and exposure to smoke, fire and flames, where rates were not significantly higher in the cohort population. Rates were significantly lower for contact with venomous animals and plants. Similarly, rates were significantly higher for most specific external causes.
- When comparing rates between housing applicants and housing tenants, hospitalisation rates were similar for most categories of external cause and specific types of external cause. The only exceptions were intentional self-harm which was significantly more common among housing applicants, and exposure to inanimate mechanical forces which was marginally less common among the housing applicants.

### 9.2.5 Age-ethnicity standardised causes of admissions

The above analyses were repeated but with rates age-ethnicity-standardised to the population structure of the cohort study at cross section June 2005 (to improve the stability of estimates). This analysis used age in 10-year groups if under 70, then 70+. Ethnic group were: Maori, Pacific, NZ European, Asian and other combined, and not stated (see Table 12.1 for standard population used). This analysis was based on exclusive coding i.e. prioritised ethnicity. These analyses again used the standard filter (based on principal diagnosis with exclusion of nonhospitalisations, waiting-list admissions, irrelevant conditions, and one-month readmissions).

It is important to note that age-ethnicity-standardised rates may be unreliable. The population was divided into age-ethnicity groups, some of which had small or zero events (especially when analysing selected diseases in the relatively smaller housing applicant population). Also the ethnic response of a person may be inconsistent or change between NA and IRR forms, NMDS data and Census data (see section 4.4.2). Consequently, where the total number of cases was $<10$, rates have not been presented.

These results are presented in graphical and tabular form.

- The overall consequence of using age-ethnicity standardisations is shown in Figure 9.50 and Table 12.19.
- For broad ICD. 10 categories, a comparison of age-ethnicity standardised hospitalisation rates in the cohort population compared with the other $N Z$ population is show in Figure 9.51 and Table 12.20.
- For broad ICD. 10 categories, a comparison of age-ethnicity standardised hospitalisation rates in housing applicants compared with housing tenants is show in Figure 9.53 and Table 12.21.
- For specific diseases, a comparison of age-ethnicity standardised hospitalisation rates in the cohort population compared with the other NZ population is show in Table 12.22.
- For specific diseases, a comparison of age-ethnicity standardised hospitalisation rates in housing applicants compared with housing tenants is shown in Table 12.23.

This analysis showed the following:

- The use of age-ethnicity-standardised results reduced the rate ratio different between the cohort population and the other $N Z$ population (from RR 1.67 to 1.47 ), which suggests that a fairly substantial part (about $30 \%$ ) of this difference could be explained by the relatively high proportion of Maori and Pacific people in the cohort population.
- When comparing the cohort population with the other NZ population according to major disease categories there was, not surprisingly, a decrease in the rate ratio difference for most disease categories. This change was particularly marked for endocrine, nutritional and metabolic diseases, respiratory diseases and skin and subcutaneous diseases, again showing that some of the differences seen in the cohort population are caused by the composition of this population. Rates for some major diagnostic categories stayed very similar, notably for neoplasms, blood and immune system disorders, and nervous system disorders. Even with this additional adjustment, the cohort population continued to experience significantly higher hospitalisation rates than the other $N Z$ population for all major disease categories except congenital diseases.
- When comparing the cohort population with the other NZ population for specific diseases, there was again a decrease in the rate ratio difference for many specific diseases following age-ethnicity standardisation. For some diseases, this form of standardisation reduced the difference to non-significance, notably meningococcal disease, acute bronchitis, and malignant neoplasms of the stomach. In the case of acute bronchiolitis, this standardisation actually reversed the association so that this disease had a higher rate in the other NZ population compared with the cohort population. For a minority of diseases, this standardisation resulted in an increase in rate, notably for intestinal infectious diseases, demyelinating diseases of the $C N S$, some mental and behavioural disorders (depressive, neurotic, personality, and disorders due to psychoactive substance use, and disorders of childhood or adolescences) and some specific injuries (fractures of shoulder, upper arm and fractures of the forearm).
- Age-ethnicity-standardisation also increased the hospitalisation rate in the housing applicants compared with the housing tenants (from RR 1.06 to 1.10 ) which is understandable, given the higher proportion of Pacific people who are tenants compared with the applicant population.
- When comparing the housing applicants with the housing tenants according to major disease categories, this standardisation resulted in rates becoming significantly higher in some categories (Figure 9.53). In particularly, infectious and parasitic diseases and respiratory diseases now had significantly higher rates in the applicants compared with housing tenants. Applicants now no longer had significantly lower rates for diseases of the ear and mastoid and skin and subcutaneous diseases. They also no longer had significantly higher rates of congenital disease. The higher rates for mental and behavioural diseases also decreased, though remained significantly higher in the housing applicants, suggesting that some of this difference was due to the ethnic composition of the applicant population. Housing applicants continued to have significantly lower rates of neoplasms, which was the only disease grouping where this difference was seen.
- When comparing the housing applicants with the housing tenants for specific diseases, this standardisation resulted in rates becoming significantly higher for several specific diseases, including viral infection of unspecified site, other chronic obstructive pulmonary disease, and burns and corrosions. Some other rate ratios increased to the point that previously lower rates in housing applicants no longer applied, notably other septicaemia, and cutaneous abscess, furuncle and carbuncle. Rate ratios dropped for fracture of shoulder
and upper arm, superficial injury of lower leg and for falls to the point where rates for these conditions were significantly lower in housing applicants (though only marginally so).

Figure 9.50: Comparison of crude, age-standardised and age-ethnicity-standardised rates in housing applicants and housing tenants, compared with other NZ population, based on filtered hospitalisations, May 2003 to June 2005

Figure 9.52: Hospitalisation age-ethnicity-standardised rate ratios in housing applicants and housing tenants, compared with other $N Z$ population, according to major disease categories, May 2003 to June 2005

Figure 9.53: Hospitalisation age-ethnicity-standardised rate ratios in housing applicants compared with housing tenants, according to major disease categories, May 2003 to June 2005

### 9.2.6 Comparison of applicants with recent tenants

The above analyses were repeated for housing applicants and housing tenants, but with (a) housing applicants restricted to those who subsequently became tenants and (b) housing tenants restricted to their first 12 -months (i.e. only events and person time that occurred within 12 months of becoming a HNZC tenant were counted). Rates were age-standardised to the population structure of the 2001 census, and again used the standard filter (based on principal diagnosis with exclusion of 'non-hospitalisations', waiting-list admissions, irrelevant conditions, and one-month readmissions).

These results are presented in graphical and tabular form.

- Age-standardised disease rates in housing applicants (who subsequently became tenants), housing tenants (during their first 12-months), and the other NZ population, according to broad ICD. 10 categories (Figure 9.54).
- A comparison of age-standardised disease rate ratios in housing applicants (who subsequently became tenants), housing tenants (during their first 12-months), and the other $N Z$ population, according to broad ICD. 10 categories (Figure 9.55, Table 12.24).
- A comparison of age-standardised disease rate ratios in housing applicants (who subsequently became tenants) and housing tenants (during their first 12-months) according to specific diseases (Table 12.25)

This analysis showed the following:

- There is no change in the hospitalisation rate when comparing the sub-group of housing applicants who subsequently became tenants, and housing tenants during their first year of tenancy (rate ratio $1.00,95 \% \mathrm{CI} 0.93,1.07$ ). This finding suggests no immediate health effects are associated with the move from waiting list to tenant. However, this finding will be investigated more fully in the future using longitudinal analysis.
- In terms of major disease categories, hospitalisations for nervous system conditions were significantly more common among housing applicants (which was not the case when comparing the total housing applicant and total housing tenant populations) and neoplasms were significantly more common among housing tenants (this pattern was more marked than when comparing the total housing applicant and total housing tenant populations).
- Some specific conditions also varied. Acute bronchiolitis had markedly higher rates among housing applicants. Some conditions had marginally elevated rates in housing applicants, including injuries to abdomen, back and pelvis, and poisonings and toxic effects. Hospitalisations were significantly lower for cutaneous abscess, furuncle and carbuncle among the housing applicants.

Figure 9.54: Hospitalisation age-standardised rates in housing applicants (who subsequently became tenants), compared with housing tenants (during their first 12 months of tenancy time) and the other $N Z$ population according to major disease categories, May 2003 to June 2005

Figure 9.55: Hospitalisation age-standardised rate ratios in housing applicants (who subsequently became tenants), compared with housing tenants (during their first 12 months of tenancy time) according to major disease categories, May 2003 to June 2005

### 9.2.7 Comparison of hospitalisation rates by duration of tenancy

This section examines changing patterns of hospitalisation according to the duration of the tenancy.

It divides housing tenants into the following time periods:

- Pre-tenancy ie Applicants who become tenants
- Tenants $<1$ years
- Tenants 1-3 years
- Tenants 4-6 years
- Tenants 7-9 years
- Tenants $10+$ years

For the housing tenants with multiple leases, only the last lease was considered. Rates were age-standardised to the population structure of the 2001 Census, and again used the standard filter (based on principal diagnosis with exclusion of non-hospitalisations, waiting-list admissions, irrelevant conditions, and one-month readmissions). Rates are presented for the following:

- Total hospitalisation, based on use of the standard filter (Figure 9.56, Table 12.26)
- Major disease categories (Figure 9.57, Table 12.26)
- Selected specific diseases (Figure 9.58 to Figure 9.61, Table 12.27)

This analysis shows that hospitalisation rates are highest among housing applicants who will become tenants and housing tenants during their first year as tenants (both about 277 per 1,000 per year). Hospitalisation rates are less for longer-term tenants (1-3 years) and reach a plateau for those who are housing tenants for 4 or more years (about 182 per 1,000 per years). This hospitalisation rate remains significantly higher than that seen for the other $N Z$ population (about 127 per 1,000 per year).

The pattern seen for major disease categories is broadly similar, with a decline from highest rates as housing applicants or housing tenants during the first year of the tenancy to lower rates with longer periods spent as HNZC tenants. The only exceptions are neoplasms and congenital conditions where rates remain relatively constant with duration of tenancy.

Figure 9.56: Total age-standardised hospitalisation rates in housing tenants according to duration of tenancy, compared with housing applicants and other $N Z$ population, May 2003 to June 2005

Figure 9.57: Age-standardised hospitalisation rates in housing tenants according to duration of tenancy, compared with housing applicants (who become tenants) and other
$N Z$ population, According to major disease categories, May 2003 to June 2005

The pattern seen for selected diseases is more mixed. Some diseases have a very pronounced decline in hospitalisation rates with duration of tenancy. This is particularly the case with mental health conditions, intentional self-harm, assault, and poisonings and toxic effects (some of which will be self-inflicted). Several of the infectious and parasitic diseases also show a decline in hospitalisation rates with duration of tenancy. This decline is most marked for the intestinal infectious diseases, acute bronchiolitis, other chronic obstructive pulmonary disease, and asthma. However, it must be noted that the population living in a HNZC rental property for $>3$ years will be different to short-term residents. However, it must be noted the the population living in a HNZC house for $\geq 3$ years wil be different to those who stay for a shorter period. That is why the future longitudinal analyses that follow the same individuals for a longer period of time will be so important.

Figure 9.58: Age-standardised hospitalisation rates in housing tenants according to duration of tenancy, compared with housing applicants and other NZ population, for selected infectious diseases, May 2003 to June 2005

Figure 9.59: Age-standardised hospitalisation rates in housing tenants according to duration of tenancy, compared with housing applicants and other NZ population, for selected respiratory diseases, May 2003 to June 2005

Figure 9.60: Age-standardised hospitalisation rates in housing tenants according to duration of tenancy, compared with housing applicants and other $N Z$ population, for selected injuries, May 2003 to June 2005

Figure 9.61: Age-standardised hospitalisation rates in housing tenants according to duration of tenancy, compared with housing applicants and other NZ population, for selected mental health conditions, May 2003 to June 2005

### 9.2.8 Comparison of hospitalisation rates by prioritisation

The following analysis (Figure 9.62, Table 12.28) compares age-standardised hospitalisation rates in sub-groups of housing applicants, notably a comparison of higher priority ( $\mathrm{A}+\mathrm{B}$ ) with lower priority $(\mathrm{C}+\mathrm{D})$ applicants. This analysis shows that the population prioritised for social housing has a $44 \%$ higher hospitalisation rate ( 266 per 1000 per year) compared with those assigned a lower priority ( 185 per 1000 per year). However, even the lower priority applicants $(\mathrm{C}+\mathrm{D})$ have a markedly higher hospitalisation rate than the other $N Z$ population (about 127 per 1,000 per year).

Figure 9.62: Age-standardised hospitalisation rates in sub-groups of housing applicants $(\underline{A+B}, C+D)$ compared with housing tenants and other $N Z$ population, May 2003 to June 2005

### 9.2.9 Sensitivity analysis based on restricting to overnight admissions

Restricting the analysis to overnight hospitalisations has some advantages. These events are likely to represent a more consistent (and higher) threshold for measuring health outcomes across New Zealand and across diverse populations. Such events also correspond more closely to what many would consider to be the meaning of being hospitalised. From a resource perspective, such events also represent a markedly higher quantum of resources that would be expended on a day case.

This analysis has been carried out according to major disease categories (Table 12.29, Table 12.30 ) and specific diseases (Table 12.31, Table 12.32). Rates were age-standardised to the population structure of the 2001 Census, and again used the standard filter (based on principal diagnosis with exclusion of 'non-hospitalisations', waiting-list admissions, irrelevant conditions, and one-month readmissions). In this instance, the additional filter of overnight admission was added which reduced the total events by about $25 \%$.

Results of this analysis showed the following:

- Overall, the study findings were not particularly sensitive to the use of this more restricted definition of a hospitalised event. Given that this restriction reduced the recorded events, there was a corresponding increase in the width of the confidence interval, which was particularly noticeable for the relatively small population of housing applicants.
- When comparing this narrower definition of hospitalisation, the rate in the cohort population dropped from 212 to 162 per 1,000 per year, which was similar to the fall in rates for the other $N Z$ population (from 127 to 95 per 1,000 per year). Consequently, the rate ratio for hospitalisations in the cohort population compared with other $N Z$ population remained virtually unchanged (it increased slightly from 1.67 to 1.70 ).
- When comparing the cohort population with the other $N Z$ population according to major disease categories there was little effect, with hospitalisation rates remaining significantly elevated for all categories, except congenital diseases.
- When comparing the cohort population with the other $N Z$ population according to specific diseases, there were few important changes in effect sizes, though the confidence intervals were broader. The rate ratio for hospitalisation for acute laryngitis and tracheitis for example increased and was significantly higher in cohort population compared other $N Z$ population. Rate ratios for some groups of injuries, such as injuries to neck and injuries to abdomen, back and pelvis decreased and become non-significantly higher in the cohort population.
- For housing applicants compared with housing tenants, there was also only a small impact from using this more restricted definition of hospitalisation, with hospitalisation rates dropping in housing applicants from 218 to 165 per 1000 per year compared with a drop from 210 to 161 per 1,000 per year in housing tenants. The rate ratio dropped from 1.06 to 1.03 , but remained significantly higher, but only marginally so.
- When comparing the housing applicants with the housing tenants according to major disease categories, there tended to be a decrease in the rate ratios for housing applicants. Housing applicants continued to have significantly higher hospitalisation rates for mental and behavioural conditions and congenital diseases. Rates also remained higher for blood and immune system, ear and mastoid, and injury and poisonings, but the wider confidence interval meant that these differences were no longer significant. Housing applicants continued to have significantly lower rates for diseases of the skin and subcutaneous tissues than housing tenants.
- When comparing the housing applicant population with the housing tenant population according to specific diseases there were few important changes in effect sizes, though the confidence intervals were broader which affected the significance of some findings. Using this more restricted definition of hospitalisation for asthma, for example, decreased the rate ratio from $1.18(95 \%$ CI $1.03,1.36)$ to $1.09(95 \%$ CI $0.92,1.30)$ so hospitalisation rates were no longer significantly higher in the housing applicant population. This result would also suggest that housing applicants were receiving disproportionably more of their asthma treatment as day cases compared with housing tenants. The opposite pattern was seen for bronchitis where the rate ratio increased with the more restricted definition of hospitalisation. Some categories of injury where rates were lower in housing applicants became more marked with the more restricted definition, notably fractures of shoulder and upper arm, falls and contact with sharp glass, all of which became significantly lower in the housing applicants compared with the housing tenants after restricting hospitalisations to overnight cases.

### 9.2.10 Potentially avoidable hospitalisations

The following analysis of potentially avoidable hospitalisations (PAH) is intended to provide an indication of the total burden of hospitalisations that could be avoided through unrestricted access to completely effective prevention and treatments services. As a result, the hospitalisation data are only filtered to remove overseas visitors and non-hospitalisations (unlike the previous analyses which were based on 'standard hospitalisations'). PAH include two components:

- Avoidable hospitalisations - Based on selected ICD. 10 codes from A00-R99 as used in previous analyses.
- Injuries and poisonings - Based on ICD. 10 codes S00-T98. These events are regarded as entirely preventable, by definition

Results are show in Figure 9.63 and Table 12.33. As this analysis shows, rates of PAH are very much higher in housing applicants and housing tenants compared with the other NZ population.

Figure 9.63: Potentially avoidable hospitalisations, age-standardised hospitalisation rates in housing applicants, housing tenants and Other NZ population

### 9.2.11 Hospitalisation rates by crowding level

This report includes a preliminary analysis of hospitalisation rates by level of household crowding. This follows a similar format to other results presented in this section with an overall analysis of rates, followed by analysis according to major diagnostic categories then specific diseases of interest. In this case, the comparison is between households reported as crowded using CNOS and uncrowded. Crowded households are also divided into those with one bedroom deficit, and $2+$ bedroom deficit. This analysis focused on the cohort (combined applicant and tenant households) but also examined housing applicants and housing tenants separately to see if the health impact of household crowding is different in these two groups. To simplify the analysis, each cohort participant was assigned the crowding level recorded in his or her most recent NA or IRR. Because levels of household crowding are already known to be highly associated with ethnicity, this analysis used age-ethnicity standardised rates.

These results are presented in graphical and tabular form.

- Hospitalisation rates in crowded and uncrowded housing applicant, housing tenant and cohort (applicant and tenant) households are shown in Table 12.34.
- Hospitalisation rates according to crowding level (uncrowded, 1 bedroom deficit and $2+$ bedroom deficit based on CNOS) for housing applicant, housing tenant and cohort (applicant and tenant) households are shown in Figure 9.64 and Table 12.35.
- For broad ICD. 10 categories, a comparison of crowded and uncrowded households is shown for housing applicants (Table 12.36), housing tenants (Table 12.37) and the cohort population (applicants and tenants combined, Table 12.38). Age-ethnicity standardised rates for the cohort population are shown in Figure 9.65 and rate ratios for cohort in Figure 9.66
- For specific diseases, a comparison of age-ethnicity standardised rates in crowded and uncrowded households in the cohort population (applicants and tenants combined) is shown in Table 12.39.

This analysis showed the following:

- For housing applicants, hospitalisation rates were similar for those classified as crowded as for those who were uncrowded.
- For housing tenants, hospitalisation rates were significantly higher for those classified as crowded, and considerably elevated for those with a 2 or more bedroom deficit (RR 1.19, $95 \%$ CI 1.14, 1.26). Results were similar for combined housing applicants and housing tenants.
- For combined housing applicants and housing tenants, hospitalisation rates were significantly elevated for those classified as crowded for several major disease categories, particularly neoplasms, musculoskeletal and connective tissue diseases and skin and subcutaneous diseases. Conversely, hospitalisation rates for crowded households were significantly less than for uncrowded households for mental and behavioural disorders.
- For specific diseases, hospitalisation rates were ignorantly elevated in those households classified as crowded for some infectious diseases, including bacterial infection of unspecified site, shingles (zoster), acute bronchiolitis and most forms of skin infection (cutaneous abscess, furuncle and carbuncle, other local infection of skin and subcutaneous tissue, and osteomyelitis). Of note were the significantly higher rates for acute myocardial infarction and heart failure. Injuries to wrist and hand and injuries to hip and thigh were all significantly more common causes of hospitalisation in crowded households. External causes that were also significantly more common were falls and exposure to inanimate
mechanical forces. Interestingly, hospitalisations for mental disorders due to psychoactive substance use and manic episode or bipolar disorder were significantly less common in crowded households, whereas the opposite pattern was seen for admissions diagnoses as adult personality disorders.

Figure 9.64: Comparison of age-ethnicity-standardised hospitalisation rates in housing applicants, housing tenants and cohort (applicant and tenants), according to different crowding levels (uncrowded, 1-bedroom deficit, 2+ bedroom deficit), May 2003 to June 2005

Figure 9.65: Comparison of age-ethnicity-standardised hospitalisation rates in crowded and uncrowded cohort (applicant and tenant) households, according to major disease categories, May 2003 to June 2005

Figure 9.66: Hospitalisation age-ethnicity-standardised rate ratios in crowded and uncrowded cohort (applicant and tenant) households, according to major disease categories, May 2003 to June 2005

### 9.2.12 Hospitalisation rates for active smoking adults

This report includes a preliminary analysis of hospitalisation rates in those tenants who reported that they were active smokers (one or more cigarettes a day) compared with those who reported they were non-smokers. This analysis is based on tenants over 19 years ( $52.6 \%$ of total tenants) and those who completed the question ( $69.1 \%$ of tenants $>19$ years). This gave a total sample size of 60261 tenants.

These results are presented in graphical and tabular form.

- Overall crude, age-standardised, and age-ethnicity-standardised hospitalisation rates in active smoking and non-smoking housing tenants is shown in Table 12.40.
- For broad ICD. 10 categories, a comparison of smoking and non smoking housing tenants is shown in Figure 9.67, Figure 9.68 and Table 12.42 for age-standardised rates and rate ratios, and Figure 9.69, Figure 9.70 and Table 12.43 for age-ethnicity standardised rates and rate ratios.
- For specific diseases, a comparison of age-standardised rates and age-ethnicity standardised rates in smoking and non-smoking housing tenants is shown in Table 12.44 and Table 12.45 .

This analysis showed the following:

- In housing tenants, age-standardised hospitalisation rates were significantly elevated among smokers compared with non-smokers (RR 1.15, $95 \%$ CI 1.11, 1.18). The increase was only marginal when the comparison was based on age-ethnicity standardised rates (RR 1.04, $95 \%$ CI 1.00, 1.07).
- Age-standardised hospitalisation rates were significantly elevated for smokers for several major disease categories, including neoplasms, respiratory diseases, skin and subcutaneous diseases, and external causes. The association between smoking and hospitalisation rates
was particularly marked for mental and behavioural disorders. Using age-ethnicity standardised rates, the association with smoking was less marked, and only persisted for neoplasms, mental and behavioural disorders and injuries and poisonings. Conversely, age standardises and age-ethnicity standardised hospitalisation rates for smokers were significantly less than for non-smokers for infectious and parasitic diseases, diseases of the eye and adnexa, and diseases of the circulatory system.
- For specific diseases, age-standardised and age-ethnicity standardised hospitalisations rates were significantly elevated for acute tonsillitis, chronic obstructive pulmonary disease, cutaneous abscess, furuncle and carbuncle, most groups of mental and behavioural disorders, poisonings and toxic effects, fracture to wrist and hand, intentional self harm and assault.

Age-ethnicity-standardised Rate Ratios

### 9.2.13 Hospitalisation rates for passive smoking children

This report includes a preliminary analysis of hospitalisation rates for children under 15 years old that compares those in non-smoking household (all adults in household responded to the smoking question as 'No") with those in smoking households (at lest one adult over 18 years in household responded to the smoking question as 'Yes'). This analysis is based on tenants under 15 years ( $38.4 \%$ of total tenants) and those whose household members completed the smoking questions ( $42.1 \%$ of tenants $<15$ years). This gave a total sample size of 48908 tenants.

These results are presented in graphical and tabular form.

- Overall crude, age-standardised, and age-ethnicity-standardised hospitalisation rates in smoking household and non-smoking households are shown in Table 12.40.
- For broad ICD. 10 categories, a comparison of smoking and non-smoking households is shown in Figure 9.71 and Figure 9.72 and Table 12.46 for age-standardised rates and rate ratios, and Figure 9.73 and Figure 9.74 and Table 12.47 for age-ethnicity standardised rates and rate ratios.
- For specific diseases, a comparison of age-standardised rates and age-ethnicity standardised rates in smoking and non-smoking households is shown in Table 12.48 and Table 12.49.

This analysis showed the following:

- In housing tenants, age-standardised and age-ethnicity standardised hospitalisation rates were not significantly elevated for children in smoking compared with non-smoking households.
- Age-standardised and age-ethnicity standardised hospitalisation rates were significantly elevated for children in smoking households compared with non-smoking households for diseases of the blood and immune system, and musculoskeletal and connective disorders. Age standardises and age-ethnicity standardised hospitalisation rates for children in smoking households compared with non-smoking households were marginally lower for respiratory diseases.
- For specific diseases, age-standardised and age-ethnicity standardised hospitalisations rates were significantly elevated for children in smoking households compared with nonsmoking households for cellulitis.
And some specific injuries (injuries to hip and thigh and fracture of femur).

## 10 Discussion

### 10.1.1 Main findings

The first 29 months operation of the Housing Crowding and Health Study has demonstrated that the study is technically feasible and likely to be able to investigate all of its planned objectives. In particular:

- HNZC administrative data can be successfully transferred via NZHIS in a form that enables analysis of the characteristics of individuals and households.
- Most (92\%) housing applicants and housing tenants can be matched to their national health index (NHI) number, which is the key to linking to hospitalisation records.
- Most ( $93 \%$ ) of applicants and tenants can be followed in a way which allows their 'person time' to be accurately assigned to applicant and tenant categories.
- New and modified questions on the NA and IRR forms are being successfully completed in the majority of cases (though the voluntary smoking question is still only completed by $63 \%$ ).
- Housing applicants are exposed to significantly higher levels of household crowding than housing tenants, who are in turn living in more crowded conditions than the other $N Z$ population. Crowding levels are particularly high for housing applicants sharing houses with non-applicants households.
- The majority ( $61.6 \%$ ) of housing applicants who become housing tenants decrease their level of household crowding in the process, and this decrease is marked.

The analysis of hospitalisation data identified a number of important characteristics of the cohort populations:

- Social housing applicants and tenants have very high rates of recorded contact with the hospital system. These events are equivalent to 399/1000/year for housing applicants and 348/1000 for housing tenants, compared with 218/1000 for the other NZ population.
- The standard filter (excludes overseas visitors, non-hospitalisations, waiting list admissions, irrelevant conditions and one-month readmissions) removes $50 \%$ of recorded hospital contacts. After this filter is applied, hospitalisations remain markedly higher for the housing applicants (223/1000) and housing tenants (210/1000) compared with other NZ population (127/1000).
- The cohort population has significantly higher hospitalisations rates than the other NZ population for all age groups, and for males and females. They also have higher rates for European, Maori, and Pacific people.
- Surprisingly, hospitalisation rates were significantly higher for the highest income quintile of housing applicants, whereas there was a slight negative gradient for housing tenants with higher income associated with a lower hospitalisation rate. Similarly, there was a modest increase in hospitalisation rates for housing tenants living in the most deprived neighbourhoods where these properties are concentrated (42\% are in NZDep 2001 category 10)
- There are significant differences in hospitalisation rates between HNZC regions. HNZC properties are disproportionately located in urban areas compared with rural areas. Hospitalisations rates are lower for those in satellite urban areas, and non-significantly higher in rural areas. Hospitalisations follow a familiar seasonal pattern with higher rates in winter, particularly for housing applicants.
- Age-standardised rates for the cohort population in total (housing applicants and tenants), compared with the other $N Z$ population, were significantly elevated for every disease grouping except for congenital diseases. Such differences were largest for endocrine, nutritional and metabolic diseases, mental and behavioural conditions, respiratory diseases, and skin and subcutaneous diseases.
- Age-standardised rates for the cohort population were also elevated for virtually every specific disease included in the analysis. Specific examples where rates were elevated two fold or more included: Infectious diseases (tuberculosis, meningococcal disease, septicaemia, all forms of viral hepatitis); Respiratory diseases (pneumonia, bronchitis, chronic obstructive pulmonary disease, other lower respiratory infections, asthma); Skin and bone infections (impetigo, cutaneous abscess, cellulitis, lymphadenitis, osteomyelitis); Other diseases with an infectious origin (acute rheumatic fever, acute and unspecified nephritis syndrome); Cardiovascular diseases (hypertensive diseases, heart failure); Injuries (from contact with heat, assault, pedestrian injuries, dog bites, sharp glass); Mental and behavioural disorders (most categories, plus intentional self-harm).
- By contrast, housing applicants and housing tenants generally had similar rates of hospitalisation for most groups of diseases and specific diseases. However, housing applicants had significant higher rates of hospitalisation for some diseases: Respiratory diseases (notably acute pharyngitis, acute bronchitis, acute bronchiolitis and asthma); Mental and behavioural disorders (particularly mood disorders, neurotic and stress related disorders, mental disorders due to psychoactive substance use, plus intentional self harm); and certain injuries (notably poisonings and toxic effects).
- By contrast, housing applicants had lower hospitalisation rates for some conditions, notably some skin infections (abscess, furuncle and carbuncle)
- Carrying out the analysis using age-ethnicity standardised rates removed some of the effects that were related to the different ethnic composition of the housing applicant and housing tenant populations compared with the other $N Z$ population. The use of age-ethnicity-standardised results reduced the rate ratio different between the cohort population and the other $N Z$ population by about $30 \%$ suggesting that some of this difference could be explained by the relatively high proportion of Maori and Pacific people in the cohort population. Even with this additional adjustment, housing applicants and housing tenants continued to experience significantly higher hospitalisation rates than the other $N Z$ population for all major disease categories except congenital diseases. For some specific diseases, this form of standardisation reduced the difference to non-significance, notably meningococcal disease, acute bronchitis, and malignant neoplasms of the stomach. For a minority of diseases, this standardisation resulted in an increase in rate, notably for intestinal infectious diseases, demyelinating diseases of the CNS, some mental and behavioural disorders and some injuries. Age-ethnicity-standardisation also increased the hospitalisation rate in the housing applicants compared with the housing tenant populations (from RR 1.06 to 1.10 ) which is understandable, given the higher proportion of Pacific people who are housing tenants compared with the housing applicant population. This standardisation resulted in rates becoming significantly higher for housing applicants in some disease categories, particularly infectious and parasitic diseases and respiratory diseases. Applicants now no longer had significantly lower rates for diseases of the ear and mastoid and skin and subcutaneous diseases. They also no longer had significantly higher rates of congenital disease. Housing applicants continued to have significantly lower rates of neoplasms, which was the only disease grouping where this difference was seen. When comparing the housing applicants with the housing tenants for specific diseases, this standardisation resulted in rates becoming significantly higher for several specific diseases, including viral infection of unspecified site, other chronic obstructive pulmonary disease,
and burns and corrosions. Some other rate ratios increased to the point that previously lower rates in housing applicants no longer applied, notably other septicaemia, and cutaneous abscess, furuncle and carbuncle. Rate ratios dropped for fracture of shoulder and upper arm, superficial injury of lower leg and for falls to the point where rates for these conditions were significantly lower in housing applicants (though only marginally so).
- Restricting the definition of hospitalisation to overnight hospitalisation removed about $25 \%$ of events that involved attending as a day case. This restriction had little effect on the key findings.
- A better indication of the health effects of social housing can be obtained by comparing hospitalisation rates in the sub-group of applicants who subsequently became tenants, and tenants during their first year of hospitalisation. These populations had exactly the same overall hospitalisation rates (rate ratio $1.00,95 \%$ CI $0.93,1.07$ ). This finding suggests no immediate health effects are associated with the move from waiting list to tenant. However, this finding will be investigated more fully in the future using longitudinal analysis. These populations had very similar rates of hospitalisation for major disease categories and specific diseases. The only differences were that hospitalisations for nervous system conditions were significantly more common among housing applicants (which was not the case when comparing the total housing applicant and total housing tenant populations) and neoplasms were significantly more common among housing tenants (this pattern was more marked than when comparing the total applicant and total tenant populations). Acute bronchiolitis had markedly higher rates among housing applicants. Some conditions had marginally elevated rates in housing applicants, including injuries to abdomen, back and pelvis, and poisonings and toxic effects. Hospitalisations were significantly lower for cutaneous abscess, furuncle and carbuncle among the housing applicants.
- Extending this analysis, it is also useful to look at hospitalisation rates according to duration of tenancy. This analysis shows that hospitalisation rates are highest among housing tenants during their first year as tenants ( 277 per 1,000 per year). Hospitalisation rates decline over the subsequent 1-3 years as tenants, and then reach a plateau for those who are tenants for 4 or more years (about 182 per 1,000 per years). This hospitalisation rate remains significantly higher than that seen for the other $N Z$ population (about 127 per 1,000 per year). The pattern seen for major disease categories is broadly similar, with a decline from highest rates as housing tenants during the first year of the tenancy to lower rates with longer periods spent as HNZC tenants. The only exceptions are neoplasms and congenital conditions where rates remain relatively constant with duration of tenancy. The pattern seen for selected diseases is more mixed. Some diseases have a very pronounced decline in hospitalisation rates with duration of tenancy. This is particularly the case with mental health conditions, intentional self-harm, assault, and poisonings and toxic effects (some of which will be self-inflicted). Several of the infectious diseases also show a decline in hospitalisation rates with duration of tenancy. This decline is most marked for the intestinal infectious diseases, acute bronchiolitis, chronic obstructive pulmonary disease, and asthma.
- This analysis also reviewed the health outcomes associated with the HNZC prioritisation system, which distinguished higher priority housing applicants ( $\mathrm{A}+\mathrm{B}$ ) from lower priority housing applicants ( $\mathrm{C}+\mathrm{D}$ ). This analysis shows that the population prioritised for social housing has a $44 \%$ higher hospitalisation rate ( 266 per 1000 per year) compared with those assigned a lower priority ( 185 per 1000 per year). However, even the lower priority applicants have a markedly higher hospitalisation rate than the other NZ population (about 127 per 1,000 per year).
- Potentially avoidable hospitalisations were almost twice as high in the cohort population as compared with the other NZ population, with injuries and poisonings about $35 \%$ higher.
- This report includes a preliminary analysis of hospitalisation rates in relation to household crowding level of housing applicants and housing tenants. To simplify the analysis, each cohort participant was assigned the crowding level recorded in his or her most recent NA or IRR. Because levels of household crowding are already known to be highly associated with ethnicity, this analysis used age-ethnicity standardised rates. This analysis showed the following: For combined housing applicants and housing tenants, hospitalisation rates were significantly elevated for those classified as crowded for total hospitalisations and for several major disease categories, particularly neoplasms, musculoskeletal and connective tissue diseases and skin and subcutaneous diseases. Conversely, hospitalisation rates for crowded households were significantly less than for uncrowded households for mental and behavioural disorders. For specific diseases, hospitalisation rates were significantly elevated in those households classified as crowded for some infectious diseases, including bacterial infection of unspecified site, shingles (zoster), acute bronchiolitis and most forms of skin infection (cutaneous abscess, furuncle and carbuncle, other local infection of skin and subcutaneous tissue, and osteomyelitis). Of note were the significantly higher rates for acute myocardial infarction and heart failure. Injuries to wrist and hand and injuries to hip and thigh were all significantly more common causes of hospitalisation in crowded households. External causes that were also significantly more common were falls and exposure to inanimate mechanical forces. Interestingly, hospitalisations for mental disorders due to psychoactive substance use and manic episode or bipolar disorder were significantly less common in crowded households, whereas the opposite pattern was seen for admissions diagnoses as adult personality disorders.
- This report includes a preliminary analysis of hospitalisation rates in relation to active and passive smoking. Smoking data was reported by $69.1 \%$ of tenants $>19$ years. This group had significantly higher hospitalisation rates than non-smokers. Age-standardised hospitalisation rates were significantly elevated for neoplasms, respiratory diseases, skin and subcutaneous diseases, mental and behavioural disorders and external causes. Using age-ethnicity standardised rates, the association with smoking was less marked, and only persisted for neoplasms, mental and behavioural disorders and injuries and poisonings. Conversely, age standardises and age-ethnicity standardised hospitalisation rates for smokers were significantly less than for non-smokers for infectious and parasitic diseases, diseases of the eye and adnexa, and diseases of the circulatory system. For specific diseases, age-standardised and age-ethnicity standardised hospitalisations rates were significantly elevated for acute tonsillitis, chronic obstructive pulmonary disease, cutaneous abscess, furuncle and carbuncle, most groups of mental and behavioural disorders, poisonings and toxic effects, fracture to wrist and hand, intentional self harm and assault.
- The smoking status of household was reported for $42.1 \%$ of tenant children $<15$ years. Overall age-standardised and age-ethnicity standardised hospitalisation rates were not significantly elevated for children in smoking compared with non-smoking households. Age-standardised and age-ethnicity standardised hospitalisation rates were significantly elevated for children in smoking households compared with non-smoking households for diseases of the blood and immune system, and musculoskeletal and connective disorders. For specific diseases, hospitalisations rates were significantly elevated for cellulitis and some specific injuries.

### 10.1.2 Implications

The findings contained in this report have met the two aims of this document.
Firstly, this report shows that it has been possible to construct the cohort, successfully link applicants and tenants to their hospital records and calculate their person time in the cohort. These data can in turn be used to calculate rates of hospitalisation generally and for specific diseases. These findings have important implications for the next phase of the data analysis. In particular, they show the importance of duration of tenancy as a factor in determining hospitalisation rates. This relationship requires further investigation, ideally using longitudinal data analysis.

Secondly, this report provides a more comprehensive description of the characteristics of social housing applicants and tenants and additional information on their health status. These observations confirm that this population is highly vulnerable, at least in terms of health events resulting in hospitalisation.

- Housing applicants and housing tenants have relatively high rates of recorded contacts with the hospital system overall and for virtually every major disease grouping compared with other New Zealanders (the other $N Z$ population). These findings have implications for the effective delivery of health services to this population.
- This population also has high rates of hospitalisation for many groups of diseases that are at least partly preventable (e.g. most forms of infectious disease and injuries). This observation suggests that there could be health gain for this population, and possibly also efficiency gains for the health system, by use of a range of prevention measures that targeted social housing populations.
- Some of the diseases with particularly high rates in housing applicant and housing tenant populations have well defined environmental causes (e.g. asthma, injuries) which suggests the potential for specific prevention programmes.
- It is not possible to say from these findings whether social housing has a protective effect on those who have been housed. Housing applicants who are subsequently housed have similar rates of disease to housing tenants during their first year, suggesting no short-term health effects from social housing. However, those who have a longer duration of time as housing tenants have marked lower hospitalisation rates suggesting some protective effect from medium-term (4+ years) social housing tenancy. This could be a true protective effect. There is also a range of alternative explanations, including a selection effect where those with better health or more stable lifestyles tend to remain as tenants for longer, or a cohort effect reflecting social allocation practices that applied several years ago. This question will be investigated further with a more sophisticated longitudinal analysis.
- These findings provide some validation for the HNZC social allocation system, which aims to allocate housing on the basis of need, and assigns higher priority to applicants rated A and $B$ ahead of $C$ and $D$.
- The initial analysis of the role of household crowding supports continuing efforts by HNZC to reduce levels of household crowding in its properties.

### 10.1.3 Limitations

The findings reported here have a number of limitations:
These findings need to be interpreted with considerable caution for a number of reasons:

- Limitations with the numerator - Hospitalisations will only capture a proportion of all diseases cases. For severe diseases, such as meningococcal disease, this proportion will be high, but for less severe diseases, such as mumps, this proportion will be low and possibly biased.
- Limitations with the denominator - Accurately assigning participants (and their persontime) to the study is prone to a number of sources of error. Some of these errors reflect the limitations of using administrative data which is collected for applicant and tenant management purposes.
- Confounding - The analysis of hospitalisation data uses age-standardised rates to manage confounding by age. However, there are other confounders that have not yet been considered in the analysis (e.g. tobacco smoke exposure). There are also other unmeasured confounders that cannot be included in the analysis (e.g. there are probably unmeasured differences between tenants living in HNZC houses for <1 year compared with those who stay longer).
- Study size - Some of the diseases reported here are still relatively uncommon so findings need to be interpreted with caution. This limitation will diminish with time as the cohort size increases.
- Causal inference - This analysis treats the cohort as three cross-sections (housing applicants, housing tenants, and other NZ). The finding that some diseases have higher rates in one or other of these populations does not necessarily imply a causal association. For some conditions 'reverse' causality is operating in that those with some chronic diseases seek and are prioritised to receive social housing (e.g. multiple sclerosis). Future analyses will exploit the longitudinal nature of this cohort study to try to answer questions about whether a change in housing status is associated with a change in health status. Such analyses have much greater potential to answer such causal questions and will be the key analyses of this study.

### 10.1.4 Further work

The next stages of the analysis will include the following:

- Use of multivariable methods to adjust for measured confounders to investigate the role of household crowding more rigorously.
- Longitudinal analysis to assess the effects of a change in household crowding level which, by following the same individuals over time, provided un-confounded results.
- Further review of the impact of data quality on study findings. This review will ultimately include a sensitivity analysis to establish whether or not a validation study is needed (notably to validate key recorded variables such as the number of people living in applicant and tenant households).

'1Standard filter excludes overseas visitors, non-hospitalisations, waiting list admissions, irrelevant conditions and one-month readmissions

[^0]:    ${ }^{1}$ Turner R, Baker M, Milosevic J. Housing, Crowding and Health Study: Characteristics of Applicants and Tenants for February 2003 to June 2005. Interim Report. Housing and Health Research Programme, Nov 2004.

[^1]:    ${ }^{2}$ Data provided by Derek Adams, Information Analyst, HNZC, October 2004.

[^2]:    ${ }^{1}$ The number of smokers, non-smokers and not stated do not add to the total due to the small number of invalid observations.
    ${ }^{2}$ The response rates by ethnicity groups were calculated inclusively. This means that a person who ticked both NZ European and Maori, for example, would get counted in both groups.
    ${ }^{3}$ This does not include those of Maori ethnicity who wrote their ethnicity in the "others" category.
    ${ }^{4}$ This does not include those of Pacific ethnicity who wrote their ethnicity in the "others" category.
    ${ }^{5}$ This is calculated using the partner code in the field for the relationship to the signatory. This is different to the couples code in the IRR form.
